Notes on Perishable Table

[1] 0° or below represents the desired optimum to be maintained within the limitations of refrigeration equipment.

[2] Do not freeze.

[3] Quality lobster cannot be obtained after any period of storage; it should be purchased as a live product and it will remain satisfactory as long as it is alive and the flesh is not shrunken.

[4] If this item is to be held for periods of 3 months or less it may be carried in dry storage at moderate temperature.

[5] The length of time apples can be held successfully in cold storage will vary with the variety, district where grown, and their condition when harvested. The following data show the normal and maximum storage periods for different varieties when grown in regions to which they are adapted, picked at proper maturity, and stored immediately at 32°F. Storage life is considerably shorter at high temperatures. Ripening and deterioration is about twice as fast at 40°F as at 32°F and twice as fast again at 50° F as at 40° F. Apples should be issued while still in good condition.

Variety	Storage period (months)		Variety	Storage period (months)	
	Normal	Maximum		Normal	Maximum
Jonathan	2 to 3	4	Baldwin	4 to 5	6 to 7
Grimes Golden	2 to 3	4	Stayman Winesap	4 to 5	5 to 6
McIntosh	2 to 4	4 to 5	York Imperial	4 to 5	5 to 6
Golden Delicious	3 to 4	6	Arkansas (Black Twig)	4 to 5	6
Cortland	3 to 4	5	Northern Spy	4 to 5	6
Delicious	3 to 4	6	Rome Beauty	4 to 5	6 to 7
Rhode Island greening	3 to 4	6	Ben Davis	4 to 5	8
Yellow Newton	5 to 6	8	Winesap	5 to 7	8

8515

Table 4-14.—Safe Keeping Time and Storage Data for Perishable Subsistence Items—Continued

48.90.7

[6] Commodity not recommended for export but is suitable for immediate use by shore activities and by ships in port or shortly after sailing.

[7] Fully ripe bananas may be held at 40° F for several days with only slight discoloration of the peel and without any flavor change.

[8] Damage will result if item is stored at lower temperature than indicated.

[9] Storage temperatures of either 32° to 34° F or 50° to 55° F are recommended to avoid serious rind pittings. This defect is more severe at about 38° to 45° F than at higher or lower temperatures. A temperature of 50° to 55° F is best for control of pitting, but decay may become severe. Grapefruit may be held satisfactorily at near 32° F for about 4 weeks.

[10] Not recommended for export since the European type of grape from California with better keeping quality is available during the same period.

[11] The storage life of closely trimmed heads of lettuce packaged individually in polyethylene bags and stored at a 33° F temperature is extended much beyond the indicated 2 to 3 week period.

[12] Onions keep best at a storage temperature of about 32° F. This commodity should not be stored with items such as apples and grapefruit or an onion taste will be acquired by such items. Compartments should be kept dark.

[13] Florida type oranges keep best at 30° to 32° F. California type keep best at 35° to 37° F.

[14] The length of time fall and winter pears may be safely stored depends on the variety, when the fruit is picked, and on whether it is shipped before or after storage. Pears should be ripened for several days at 65° F before being issued for table use. Pears usually fail to soften if held at 75° to 80° F. Bartlett, Bosc, Anjou, and Comice lose their capacity to ripen normally if held in storage too long. Loss of ripening capacity occurs sooner at 36° F than at 30° F. The following data show the safe storage period for different varieties when stored at 30° or 31° F at shipping point and after shipment to market, and the approximate end of the storage season.

Storage treatment and variety	Length of storage period	End of storage period
Stored immediately after harvest:	Months	
Hardy	2 to 3	September to November
Comice	2 to 3	November to December
Bosc	3 to 3½	November to December
Kieffer	2 to 3	September to November
Anjou	5 to 6	March
Winter Nelis	6 to 7	March to May
Easter Beurre	5 to 7	March to May
Stored after 12-day transit period (precooled):		
Anjou	4 to 5	March
Hardy	2 to 3	September to November
Comice	2 to 3	November to December
Bosc	2 to 3	November to December
Winter Nelis	6 to 7	March to May

[15] Sweet potatoes are very perishable under the best conditions. Exposure to temperatures below 50° F even for a few weeks causes chilling injury and increases decay. The chilling injury causes the interior of the sweet potato to turn gray, brown, or nearly black, depending on how low the temperature is and the length of exposure.

Table 4-14.—Safe Keeping Time and Storage Data for Perishable Subsistence Items—Continued

48.90.8

[16] Potatoes will keep in good condition at 50° F for 6 to 8 weeks or longer if they are in good condition when received and if they are handled carefully during loading and stowing so as to avoid bruises and other damage. Potatoes which have been chilled prior to receipt and are then stowed in dry protected areas where temperatures do not exceed 70° F may keep for 4 to 5 weeks. Decay and sprouting is more likely to occur at higher temperatures. Potatoes stowed at temperatures of 40° to 45° F will have a storage life up to 5 months. At lower temperatures potatoes have a tendency to become undesirably sweet. A few days in 55° to 70° F storage should restore taste. Potatoes should be stored in the dark. Exposure to either natural or artificial light causes the potatoes to turn green, this green portion is bitter and unpleasant to taste and must be discarded. If temperatures below freezing are anticipated, do not store potatoes topside.

[17] Mature green tomatoes will become well colored and firm ripe in about 2 weeks at 65° F. If they are transferred at 32° F or 38° F after ripening, they may be kept another 3 weeks with little or no spoilage. Tomatoes ripened at 55° F do not keep as well as those ripened at 65° F.

[18] For several weeks storage, a rapid freezing and holding at 0° F or lower is recommended. Rapid staling occurs between 75° F and 0° F. If the bread is not to be frozen, the best storage temperature is 75° to 95° F, providing the bread is wrapped in a good quality waxed paper and efficiently sealed. Relative humidity is immaterial if the bread is wrapped and sealed properly as moisture transfer will be negligible. In the case of opened or broken wrappers, the relative humidity should be in the 80 to 85% range.

[19] Yeast, active dry is a semiperishable item and also is listed in the Nonperishable Subsistence Table.

Good stowage principles require that adequate aisles and overhead space be left clear as much as possible for the free circulation of air from the blowers. Inspect blowers to see that they are operating properly each day. Whenever one burns out, it should be reported for immediate repairs.

Defrosting Refrigerators

The refrigeration coils and units in cold storage spaces should be defrosted as often as practicable. A layer of frost or ice 1 inch or more in thickness will reduce the efficiency of the refrigeration system and may result in overloading the compressors. Bureau of Ships Technical Manual recommends defrosting before the average frost thickness reaches $^3/_{16}$ inch in the average cold storage refrigerating plant installation. Always consult the engineer officer regarding the defrosting of the refrigeration systems.

Some refrigeration units are so equipped that hot gas can be run through the cooling coil to melt the ice. Then the bulkheads, the overhead, and the deck remain cold because of the speed with which the coils are defrosted and there is no necessity for moving the food. This method of defrosting should be employed on all ships equipped with such a unit, since refrigeration in not interrupted. Check with the ship's engineer officer to see if your cold storage plant is of this type.

If your unit is not of this type, it will be necessary to remove all but the frozen items, and store them in another box. Frozen foods will not thaw in a normal defrosting period. The engineer officer will direct that the supply of refrigerant be secured to the box and the door be left open. The frost and ice will melt or they may be easily brushed off. Never use an ice pick or sharp tool to pick ice from the coils.

Once defrosting is completed, scrub and wash the box thoroughly with hot soapy water. Rinse, dry, and air the box, and return the food to its place.

SANITATION IN STORAGE SPACES

Constant attention to sanitation in provision storerooms and refrigerated spaces keeps down the number of insects and harmful bacteria, prevents waste through spoilage, and makes the storeroom an easier, more pleasant place in which to work.

You will find the following suggestions helpful in doing the job of cleaning correctly:

1. Plan your cleaning with regard to order of work and time.

8517

2. Sweep all decks of storerooms and storage boxes.

3. Remove all deck racks and scrub them with hot soapy water.

4. Add salt to water to help bleach the racks.

5. Clean decks and bulkheads with scrub brushes, a paint work rag, and hot soapy water.

6. Use a hot water hose on deck racks, wherever possible, to kill bacteria.

Additional care must be exercised in cleaning the refrigerators. Here is a suggested procedure:

1. Wait until the box is nearly empty, if possible. Then have the refrigeration cut off.

2. Remove remaining food to another refrigerated space.

3. Clean decks and deck racks. A suggested cleaning agent is baking soda and hot water, as this removes odors.

4. Leave doors open for several hours, if possible, to ventilate box.

5. If steam or water is used, be careful not to wet electrical connections or motors.

6. When the box is thoroughly aired, turn on refrigeration and replace food.

GUIDELINES FOR PROPER STORAGE

1. Inspect fresh fruits and vegetables frequently. Sort and remove decayed items.

2. Maintain the proper temperatures in the refrigerated spaces. Freeze box—0°F or lower; dairy box—30° to 32°F; chill or thaw box—36° to 38°F.

3. Maintain the proper relative humidity in the refrigerated spaces.

4. Keep fresh fruits and vegetables separated from other items which seem to absorb foreign odors.

5. Always expedite the stowing and handling of items going into the refrigerated spaces in order to conserve refrigeration and keep the products in as firm a condition as possible.

6. Consolidate breakouts so that the reefers are opened infrequently.

7. Ensure the highest standards of sanitation.

8. Maintain proper air circulation in all spaces.

9. Keep nonperishable subsistence items in dry, clean, cool spaces.

10. Inspect all storerooms frequently to discover damage or spoilage of subsistence items.

11. Avoid stacking nonperishable subsistence so high as to cause a bursting or crushing of the bottom layers.

12. Keep subsistence items away from steam or other heated pipes.

13. Use dunnage wherever possible.

14. Cross-stack to keep stacks solid and prevent toppling.

15. Keep stacks away from bulkheads and corners in order to allow for cleaning and inspections.

16. Where there are indications of rats, arrange to have appropriate rodent control.

17. Use insect repellents where the presence of insects is detected.

18. Keep products that are packed in glass or transparent containers from being exposed to light.

19. USE OLDEST STOCK FIRST (unless newer stock clearly must be used to avoid spoilage).

8518 8514

CHAPTER 5

GALLEY AND MEAT CUTTING EQUIPMENT

The food preparation and service equipment located in galley and mess spaces at naval shore stations and aboard Navy ships is designed specifically for quantity food service. To ensure safe, sanitary, and efficient operation, it is important to maintain the equipment in proper working order and to use it correctly.

GALLEY EQUIPMENT

Galley equipment is used for the final cooking and preparation of food for use in the general mess. This equipment consists of ranges, ovens, griddles, deep-fat fryers, mixing machines, meat slicing machine, cube steak machine, coffee urns, toasters, steam-jacketed kettles, steamers, steam tables, scales, refrigerators, and cooking utensils.

Although the machine driven potato peelers, food cutters, and french fry cutters, are normally located in the vegetable preparation room, they are also discussed here.

Electric Ranges

Electric ranges used in the Navy are of the following types: (1) Type A. Three surface units and one oven; (2) Type B. One surface unit and one oven; (3) Type C. Two surface units and one oven; and (4) Type S. Griddle, three-section hotplate, and a two-compartment oven. See figure 5-1 for a type S range.

Each of the above type ranges is equipped with an oven. For instructions in operation and maintenance, see electric roasting ovens.

Type A Ranges.—Surface units of older models have one of the following arrangements:

1. Three hotplates, each controlled by one three-heat switch or two single-heat switches.
2. Three griddles, each controlled by a three-heat switch and a thermostat.
3. Combinations of hot plates and griddles.

The newer models of type A ranges are equipped with three combination griddle-hotplates, each controlled by one thermostatic switch having a temperature range from 250° F to 850° F.

Type B Ranges.—Older models of type B ranges have a combination griddle-hotplate which is controlled either by one three-heat switch or by two single-heat switches.

The newer models of type B ranges are equipped with one thermostatic switch having a temperature range from 250° F to 850° F.

Type C Ranges.—The type C range has two combination griddle-hotplates. On the older models the surface units are controlled by either one or two three-heat switches.

On the newer models the surface units are controlled by one thermostatic switch having a temperature range from 250° F to 850° F.

Type S Ranges.—The type S range was developed for submarine galley use and is replacing the type B range. All the cooking, except deep-fat frying and coffee making, can be accomplished on one type S range. One of these ranges occupies the same amount of deck space as two type B ranges. The food production capacity of one type S range, however, is considerably more than twice that of the two type B ranges. The type S range permits faster and more uniform cooking and enables several sections to be used interchangeably.

A compact galley unit, the type S range consists of three separate cooking sections. The top has a griddle on the left side and a three section hotplate area on the right. A two-compartment oven section, one above the other compartment, makes up the body of the range. Dial temperature control switches are mounted on the body directly adjacent to each section. A separately mounted panel (usually bulkhead

19 SEA RAIL SUPPORT
20 SEA RAIL

Figure 5-1.—Type S. electric range.

mounted) contains additional three-heat switches for use in operating the ovens and the small hotplates.

The overall dimensions of the range are 42 inches wide (including the guard rail), 28 inches deep, and 42 inches high (to the top of the heating surfaces).

Operation of Surface Units.—Use the switch or thermostat setting at maximum heat only to heat food to cooking temperature or to bring water to boil, then reduce the switch or thermostat setting to the heat required by the food being cooked. Using more heat than necessary is not only a waste of power but produces inferior food. DO NOT leave the surface units turned on when not in use. When steaming food, keep utensils covered. The food will stick and burn if left uncovered and power will be wasted.

Care and Cleaning.—Keep the range surface units clean, and avoid spilling grease under edges of hotplates. The spaces around the surface units should be scraped clean. Remove and clean drip pans daily. Clean the range thoroughly once a week or more often if possible. The griddle hotplate type surface units can be satisfactorily cleaned by using pumice stone blocks. Use only soap and water on enameled surfaces. Although soap and water are preferable, powdered cleansers may be used on polished steel areas.

Grease filters and hoods located over galley ranges should be kept free from an excessive amount of grease. Wash the filters at least once a week. The hoods should be wiped and washed as necessary.

Wash the filters in hot soapy water in the deep sink to remove most of the grease. Then, rewash in the dishwashing machine. The preliminary washing in the deep sink will avoid an accumulation of residue in the dishwashing machine.

Electric Roasting Oven

The Navy uses four sizes of electric ovens (see fig. 5-2 for a typical oven) as indicated in the following table.

Oven Type	No. of Compartments	Capacity (lbs of meat)
60	2	120
60	3	180
125	2	250
125	3	375

Each oven section is provided with two heating units, one located at the top of the compartment and the other underneath the deck. Each heating unit is controlled by a separate three-heat switch, and the temperature of each section is regulated by a thermostat.

Operating Instructions.—Ovens should be turned on for preheating before use. To preheat, both upper and lower units of the compartment should be turned to "high" until the desired temperature is reached. Then, the thermostat control will automatically cut off the current and will supply only enough to keep the temperature constant. After heating, set the two three-heat oven switches for the proper "top" and "bottom" heat to suit the product to be baked. In roasting meat, avoid spilling grease on heating elements or thermostats, as damage to this equipment may result.

Care of Roasting Ovens.—To prevent the accumulation of foreign material, you should clean the oven thoroughly at least once a week

48.9

Figure 5-2.—Electric oven.

8521

Figure 5-3.—Electric griddle. 48.10

in addition to the normal daily cleaning. Keep door edges clean. Crusty deposits prevent proper closing of doors causing loss of heat and corrosion by the escape of steam and fumes. Use the damper lever (located above the thermostat) to prevent smoke and steam from escaping around the oven door. Do not throw water in the oven to cool it or to wash it. When cleaning the oven with a wet rag, wring the rag out thoroughly.

Electric Griddles

The griddle (fig. 5-3) consists of a cooking surface approximately 34" by 18" surrounded by a grease receptacle, supported on an enclosed body. The body is mounted on a four-leg stand with an undershelf. A griddle guard, consisting of a rectangular bottomless frame and cover, is furnished for certain types of frying such as the preparation of home fried potatoes.

The heating element of the griddle is divided into two sections. On the older models, the heating element is controlled by a three-heat switch, and on the newer model, each heating element section is controlled by a thermostatic switch.

Operation.—To operate an electric griddle, turn the control switch to high heat for 15 minutes, then to medium heat or low heat as necessary. Use the griddle guard when necessary to keep food from sliding off the cooking surface. For satisfactory operation of the griddles, you should not place frozen meat or fish on the cooking surface.

Care and Cleaning.—Keep the cooking surface scraped and wiped clean at all times. The grease gutters should always be kept clean to facilitate draining off excess grease and thereby reducing smoke. The grease receptable should be emptied frequently and thoroughly cleaned at the end of the working day.

The cooking surface can be satisfactorily cleaned with a pumice stone block. If pumice stone is not available, periodically place a cloth dampened with ordinary household ammonia on the surface when the plate is cold and allow it to remain from 4 to 5 hours. The ammonia will soften the carbon so that it is easily removed with a cloth. Care must be observed in this operation to prevent the ammonia from entering sections containing electric wiring or other electric parts, as it will destroy insulating materials. All traces of ammonia odor will disappear as the grids are heated.

Deep-Fat Fryers

The Navy now uses four sizes of deep-fat fryers. They are the types 23, 35, 51, and 90. Type 35 is obsolescent and will be discontinued when stocks are depleted. The type numbers represent the approximate number of pounds of french fried potatoes which may be prepared per hour.

Deep-fat fryers (see fig. 5-4) are heated by the immersion of electric heaters located at such a level that the portion of the fat below the heater remains comparatively cool. This allows all the sediment from the frying food to settle to the bottom of the fat container without being burned. Heating elements are controlled by a magnetic contactor and a thermostat to maintain the fat at the desired temperature.

8522

Operation of Deep-Fat Fryers.—Before you use a deep-fat fryer, make sure that the drain valve is closed tightly. When filling the fryer with fat, use the amount specified in the technical manual furnished with the fryer. Fats should be kept at least 2 inches below the fryer top. If possible, the fat should be heated and melted before placing it in the fry kettle. Cold solid fat may have moisture pockets which will explode, casting hot melted fat over a wide area. Also, if the cold fat is not uniformly distributed around the heating element, the bare portions may heat up to a point where a sudden splash of fat on the overheated element will cause the fat to burn. The fat should cover the uppermost coil at all times when the deep-fat fryer is in operation. After the fat has been added, operate the deep-fat fryer as follows:

1. Set the thermostat at the cooking temperature prescribed in the Navy-Marine Corps Recipe Service for the recipe you are using.

2. Check the temperature of the fat with the dial or hand thermometer at least once a day. The temperature should never, under any circumstances, go above 400°F.

3. Have foods as free from moisture as possible before frying. Excess moisture causes the fat to foam, sputter, and boil over. It also causes some fats to break down and shorten their useful life.

4. Do not fry bacon in the deep-fat fryer, as the fat from the bacon causes the fat level to rise above the safe level. It also contains salt which will shorten the life of the fat.

5. Follow instructions furnished with the fryer. Do not exceed the capacity of the fryer indicated on the instruction plate.

6. Deep-fat fryers must never be operated near unguarded electric sockets, sparks, or flames.

7. Guard against fire. If a fire should occur in the deep-fat fryer, notify the damage control officer immediately. UNDER NO CIRCUMSTANCES SHOULD WATER BE THROWN ON A FAT FIRE. Smother the fire with foam and place a metal cover over the deep-fat fryer as soon as possible. Keep the cover on the fryer until the fat has cooled below the ignition temperature.

8. Always turn the line switch to "OFF" when the fryer is not in use.

Figure 5-4.—Deep-fat fryer. 48.11

Cleaning of Deep-Fat Fryers.—Each fryer should be cleaned every day, if it has been in use. Before cleaning, turn off the heating element and allow the fat to cool to about 150°F. Drain the fat out of the fryer (before returning, wash if necessary). Then, remove the basket support screen, scrape off oxidized fat from the sides of the kettle with a knife, and flush down the sediment with a small amount of fat. If the kettle has become very dirty, fill it to the fat level with hot water containing dishwashing machine detergent or vinegar. Turn on the heating element and allow the water to come to a boil. Boil the water for at least 5 to 10 minutes, turn off the heating element, drain, rinse thoroughly, and dry the fry well. Clean the outside of the fry kettle with a grease solvent. DO NOT leave heating elements turned on when the deep-fat fryer is empty. This may burn out the heating element.

Electric Food Mixer

Electric food mixers are used for an infinite number of applications including beating batters

for cakes, mixing bread doughs, beating eggs, mashing and whipping potatoes, and many other uses.

Food mixing machines (fig. 5-5) are furnished in 12, 60, and 80-quart sizes with the necessary attachments, paddles and beaters (fig. 5-6). The wire beater is used for eggs, cream, and light-weight mixing; the flat beater for cake batters and medium weight mixing; the hook beater for mixing bread doughs; and the beater for medium stiff doughs.

One part of the machine revolves through the use of a set of transmission and differential gears. Various shaped paddles and mixers (fig. 5-6) can be attached to this revolving unit.

48.12

Figure 5-5.—Electric mixer.

The lower part of the mixer contains two extended adjustable arms. A bowl, containing the foods to be mixed, is placed on these arms and the arms are then moved up so the paddles will revolve through the mixture. The machines have either 3 or 4 speeds. Usually they have an attachment socket that can be used for a vegetable slicer, juicer, and meat grinder.

Operation of Electric Mixer.—Before operating the machine make sure that the bowl, paddles and/or beaters are thoroughly clean. If necessary, wash them in hot soapy water and rinse with 180°F water.

Place the ingredients in the bowl as specified on the Navy-Marine Corps standardized recipe card. Do not fill the bowl more than half full. Place the bowl in a castered dolly and move to the mixer. Do not drag the bowl across the deck. Insert the bowl in the mixing machine, making sure that the bowl ears are on the supporting pins and both sides are locked in place.

Select the proper attachment and place it in the machine. The "L"-shaped notch in the beater is to be inserted over the pin in the shaft. On the smaller models the shaft will be grooved; the attachment is inserted into these grooves and slipped into the lock. Raise the bowl to the proper height by turning the wheel or crank.

Start the motor at NO LOAD and with clutch released shift to LOW SPEED; release the clutch each time the speed is changed. The speed to be used is indicated on the recipe card and on the instructions furnished by the manufacturer. If no clutch is provided, stop the machine each time the speed is changed.

Watch mixing time and mixing speeds carefully; often blended ingredients revert to separate ingredients if mixed too long or at an improper speed. If, during the process of mixing, some of the batter has piled up on the sides of the bowl, stop the machine. Using a long handled spoon or spatula, scrape down the sides of the bowl. NEVER put spoons, spatulas, or your hands into the bowl while the machine is in operation.

When the mixing is completed, move the control switch to the OFF position and stop the motor. Lower the bowl by the lever with which you raised it, remove the beater by turning the sleeve to the left. Remove any food left on the beater with a spatula. Then, place the bowl on the castered dolly and move it to the place of use.

Some electric food mixing machines are provided with bowls of two sizes. The 20-quart

machine with both 12- and 20-quart bowls; the 60-quart machine with both 30- and 60-quart bowls and the 80-quart with 30- and 80-quart bowls. When using a smaller bowl on a large machine, an adapter must be used as well as the correct beater and/or paddle for the different size bowl. At no time should the beater or paddle scrape the bottom of the bowl.

Care and Cleaning.—The electric mixer, beaters, whips, and bowls all require care. Beaters, paddles, and bowls should be washed immediately after use. Use hot soapy water and rinse with water 180°F. Hang beaters and paddles upside down to air dry. Clean the body of the machine after each meal. Use a damp cloth or wash with water as necessary for proper sanitation. Be sure that the beater shaft is free of all dirt and food particles.

The motor and mechanical parts of the mixer are inspected and maintained by the engineering department once a week.

Coffee Urns

Coffee urns (fig. 5-7) used in Navy general messes are of the combination type, consisting of an inner compartment or tank for coffee and and outer pressure-tight tank for water. The two tanks are separated by an air space to avoid rapid temperature changes of coffee when cold water is added to the water tank. A siphon pipe

Figure 5-6.—Electric mixer attachments. 48.13

8525

Figure 5-7.—Electric coffee urns. 48.14

between the water and the spray head in the urn cover or lid forces the hot water up and sprays it over the ground coffee in the leacher. An agitating valve is provided for thoroughly mixing the coffee in the coffee tank instead of drawing it off by hand and pouring the coffee back into the urn.

Steam heated coffee urns are similar to electric urns in construction. The basic difference is that a steam coil, installed in the bottom of the water tank, provides the heating means for these urns. Electricity is required to operate the pressure type controls used on all but the 1-gallon urn to maintain the required temperatures. Operating and cleaning instructions are the same as for the electrically heated urns.

Urns are furnished in sizes for making coffee in 1-gallon (nonautomatic urn requires hand pouring), 2-gallon, and 4-gallon batches. Electric immersion heaters are installed for heating the urns, and pressure type controls are provided for automatic temperature control.

Urn bags (leacher cloths) are made of unbleached muslin. When manufactured they are treated with sizing (mainly starch). Before a new urn bag is used, it should be soaked in hot water and wrung out to remove as much sizing as possible. If this is not done, the hot water poured over the grounds will release the sizing into the coffee brew and give it an unpleasant taste.

Operation.—Inspect coffee urns inside and out before each use. Examine gage glasses, valves, and faucets for leaks, and have faults corrected before using the urns. Check the urn bags; they should be in good repair and free of coffee grounds and other agents that might make the coffee unhealthy to drink or spoil its flavor. When the inspection has been completed, you are ready to operate the urn as follows:

1. Open the cold water filling valve and fill the urn with water to the full mark on the water gage.
2. Turn the electric power switch to the "ON" position.
3. Check the pressure gage. When the indicator or the pressure gage reaches $2^1/_2$ pounds (or the premarked operating position), the urn is ready for making coffee.
4. Clamp the leacher cloth firmly on the leacher, spread ground coffee uniformly inside the leacher in the quantity required by the Navy-Marine Corps Recipe Service for the gallons of coffee to be made (quantity of ground coffee may be varied to suit the taste), and place the leacher in the top of the urn.
5. Close the urn cover or lid.
6. Open the siphon valve and allow the required volume of water to siphon over the ground coffee in the leacher. If a full batch of coffee is being made, the water will cease to siphon when the correct volume of water has been sprayed over the coffee grounds, and heavy steam will show around the urn cover.
7. Close the siphon valve.
8. Open the agitating valve slowly to the end of the stem and, without pausing, slowly close the agitating valve.
9. Open the cold water filling valve and again fill the water tank.
10. Remove the leacher, remove used coffee grounds, rinse the leacher and leacher cloth in clean cold water, and store in clean cold water until required for use again. Replace the leacher cloth at least once a week. Discoloration of the cloth does not affect its utility provided it has been properly cared for.
11. Draw the coffee as required.

12. Time the preparation of coffee so that it does not stand longer than 30 minutes before serving.

In the larger urns where automatic agitators are provided, the question of repouring coffee is never considered. However, it is necessary to mix coffee prepared in an urn because the coffee at the bottom is extracted strong, the coffee in the center is of average strength, and the coffee at the top, weak and bitter. The brew must be mixed thoroughly before it is served. To do this properly when the older type of urn is being used, remove the spent grounds after brewing and then draw off 1 gallon of brewed coffee for each pound of coffee used. Pour it back as rapidly as possible into the urn to ensure thorough mixing. NEVER pour coffee over spent grounds.

Cleaning.—When you are cleaning electrically heated coffee urns, follow the instructions listed below:

1. Heat clean water in the urn water tank by turning electric power switch on, until the pressure gage indicates $2^1/_2$ pounds, or operating pressure.

2. Close the urn cover, then open the siphon valve and siphon enough hot water to half fill the coffee tank.

3. Wash the inside of the coffee tank, top, rim, and cover, using a clean cloth. Do not use a brush or mop for washing urns having a glass-lined coffee tank. Clean the faucet, gage glass, and draw-off pipe after each use with a wet brush and with destaining compound.

4. Drain the water off by opening the coffee faucet.

5. Close the urn cover and open the siphon valve and siphon approximately 1 gallon of hot water into the coffee tank. Open the coffee faucet and then open the agitating valve for about 1 minute to sterilize the dispensing route and coffee faucet.

6. Close the coffee faucet.

7. Siphon the coffee tank half full of hot water. If the urn is being shut down for the night, allow the water to stand over night. Drain it off in the morning before use.

Clean the urn in accordance with the above instructions at the end of each day. Twice weekly, sweeten the urn by using a solution of 1 cup of baking soda to 1 gallon of hot water. Keep the baking soda solution in the urn about 15 minutes. Then agitate by opening the agitating valve for 1 minute; drain and flush thoroughly with hot water. DO NOT use cold water on glass-lined urns; always use hot water by operating the siphon valve.

Vegetable Peeler

Vegetable peelers (fig. 5-8A) have capacities of either 10-15, 30, or 50 pounds, and have a cylindrical hopper with abrasive covered wall and an abrasive covered rotary disk in the bottom. The disk has a wavy surface to agitate the vegetables in a manner that will continually present new surfaces for action by the abrasive material.

Operation.—Before loading the machine, sort the potatoes so that those in any one load are of the same size and free of stones, sticks, and other hard objects. The machine should be started and the water turned into it before any vegetables are added. Do not overload the machine. The quantity of vegetables loaded should not exceed approximately 66 percent of the total hopper capacity. A larger quantity will not be thoroughly agitated.

If the abrasive surfaces of the machine are kept reasonably clean, a charge of potatoes should

Figure 5-8.—A. Vegetable peeler, B. Vegetable cutter. 48.15

8527

be satisfactorily peeled in about 1 minute. Deep eyes or depressions in potatoes should be removed and the peeling finished with a hand peeler or small knife. It is wasteful to allow vegetables to remain in the machine longer than necessary.

Cleaning.—At the end of each day's peeling, dismantle the machine. Lift the cover off and take out the abrasive disks; remove the peel trap and strainers; wash the removed parts and the interior and exterior of the machine with hot soapy water, and rinse with water 180° F. Be sure all food particles are washed out. Reassemble the unit to be ready for use and leave the cover open for air.

Electric Vegetable Cutter

Vegetable cutters (fig. 5-8B) are electrically operated machines which, without the use of attachments or removable parts, make three classes of cuts of vegetables — shredded, sliced, and grated. A dial control on the side of the machine allows instant changing of the thickness of the cut, even while the machine is in operation.

Cleaning.—The entire front of the machine swings open to provide complete access to the interior for cleaning and blade changing. The machine should be washed with hot water immediately after use. The knurled knob holds the front securely when the machine is in operation.

Clean and scrub the knives and bowl with hot, soapy water and a very stiff brush. RINSE well with 180° F water and allow to air dry thoroughly before reassembling.

Cutter, French Fry

The cutter (see fig. 5-9) is used for cutting vegetables into cubes, slices, and french-fry shapes.

48.16

Figure 5-9.—Cutter, french fry.

By means of a hand-operated lever, the vegetables are pushed through a die containing knives that cut them into parts one-half inch thick. Different kinds of dies may be used to give cubes or slices.

When operating the cutter, make sure the dies are properly set. Keep the dies absolutely clean and dry. Clean and oil the machine after each use.

Electric Toasters

Electric toasters which you may have occasion to use are the intermittent and the continuous

48.17

Figure 5-10.—Electric toaster.

8528

type. (See fig. 5-10.) The intermittent type is composed of chrome-plated steel and has a vertical oven with from 2 to 12 top openings for inserting the bread slices. The continuous type has a chrome-plated heavy duty conveyor with motor driven revolving trays for the toast.

The accumulation of crumbs and food particles in these toasters, besides being unsanitary, may cause trouble to the heating elements. Before cleaning a toaster, be certain that the electric power is off. Then brush crumbs and charred food particles out of the heating element. If the toaster is a continuous type, the conveyor must also be cleaned. Clean metal surfaces of the toasters with a silver-dip solution at least once a week in order to keep them bright.

Steam-Jacketed Kettles

Steam-Jacketed kettles are used for cooking vegetables, boiling liquids, and making coffee. (See fig. 5-11.) They vary in size from 20 to 80 gallons. Approximately, the lower two-thirds of the kettle is surrounded by a jacket which is offset from the main kettle body to provide space for steam to circulate and heat the contents of the kettle. The kettles are stationary, mounted on three legs, and have a hinged lid or cover. They also have a tube at the bottom of the hemispherical body of the kettle, with a faucet at the outer end for drawing liquids in lieu of dipping them out, a steam inlet connection, a steam outlet connection, and a safety valve.

Figure 5-11.—Steam-jacketed kettles.

48.18

8529
8230

Kettles now in use are of three types of material—corrosion-resisting steel, aluminum, and single clad corrosion-resisting steel.

Never fill the kettle completely full. If it is necessary to stir the contents, use a metal paddle, but never leave the paddle in the kettle while cooking. Rest it across the top.

Operation.—The kettles are constructed to operate on a maximum steam pressure of 45 psi. When the pressure in the galley steam line is in excess of 45 psi, a pressure regulating valve is installed in the steam line leading to the kettles. The safety valve is adjusted to blow off at 45 pounds pressure. Do not tamper with the safety valve or tie it closed. It is there to prevent the kettle from exploding. When you heat a cold kettle, turn the steam on gradually, thus allowing the shells to become thoroughly warm before full pressure is applied. After the shells have become warm, and before applying full pressure, open the safety valve by pulling the lever. Opening the safety valve while the pressure is within the shell removes air from within the jacket, and prevents the kettle from becoming air bound.

Cleaning.—The kettles should be cleaned thoroughly after being used. Before use they should be given a rinse with hot water. The draw-off tube and fittings should be cleaned with a round brush, having a flexible wire handle and with hot water. When you clean the draw-off tube, remove the plug from the faucet. (CAUTION: Do not change plugs from one kettle to another. Each plug is machined to match its own faucet, therefore, interchanged plugs may

48.19

Figure 5-12.—Steamer.

8530

cause leakage.) Run the cleaning brush back and forth through the tube while a small stream of hot water is running through the tube. DO NOT use caustic cleaners on the kettles. The draw-off tube of older kettles is made up of several pieces, which are threaded for screwing together. To clean this type, remove the plug or cap at the back end of the draw-off, so that the cleaning brush can be run back and forth through the tube. All of the old type draw-off fittings should be removed and thoroughly cleaned at least once a week.

Steamers

Steamers (fig. 5-12) are used for steaming fish, fruit, meat, poultry, and vegetables. Most steamers used in the Navy consist of a three-door, three-compartment unit. Each unit has one or two perforated pans or baskets.

Operation.—When operating steamers you are not limited to the use of pans and baskets furnished with them. On occasions when juices are to be saved, you should cook in leakproof solid pans of a suitable size. Pans should not be overloaded; steam circulates best when pans are about three-fourths full. Different foods may be cooked in the same steam compartment without mixing unlike flavors or affecting food taste. Onions and pudding placed in individual pans may be cooked in the same steam compartment without transfer of flavor.

After the food has been placed in the steamer, close the compartment door securely. (The door latch is linked with the steam supply on most steamers, and the final movement of the lever locks the door and turns on the steam at the same time. Unlocking the door and lever turns off the steam before the door can be opened.)

If the steam supply is controlled separately, open the steam valve slowly by turning the valve wheel counterclockwise after the door is latched. Then observe the pointer on the steamer gage, which should be in the range of 5 to 7 psi. Turn the valve wheel clockwise to reduce steam pressure if it is above 7 psi.

Watch your cooking time closely and avoid spoiling food by overcooking. Less time is required for steam pressure cooking than for boiling food in water; temperature of 7 psi steam is 233°F, and boiling temperature of water is 212°F.

After cooking has been completed, turn off the steam supply by turning the valve wheel clockwise on separately controlled units, or by unlatching the compartment door of the latch-controlled steam supply. You can relieve steam pressure by operating the lever of the safety valve, if provided; otherwise, wait 2 minutes before opening the door to full open position.

Care and Cleaning.—Occasionally, when you examine the drainpipe for steam-condensate drip, none will appear after a few minutes of steamer operation. When this is the case, turn off the steam supply by unlatching the door or closing the valve, as necessary. The fault normally is stoppage in the trap, strainer, or drainpipe. To eliminate this condition; close the steam valve, remove the steam-trap strainer basket, and clean by scraping out the solids and washing the basket until the mesh or perforations are open and clear. Clean the pipe connection in the steamer compartment; reassemble the strainer and repeat the pressure cooking. If there is still no drip, the steam trap is at fault, so report this to the engineer officer via the chain of command.

After each meal, the steamer should be brush-scrubbed, washed clean with hot soapy water, and rinsed with water 180°F. Allow to air dry.

Steamtable

Steamtables (fig. 5-13) are used for serving hot foods. There are several types such as those (a) with water compartments heated by steam coils 40 psi pressure or less, (b) with steam heated water compartments and dishwarmers, (c) with water compartments heated by immersion-electric heating elements, (d) with electric heating elements, and dishwarmers, (e) with water compartments heated by gas burners, and (f) with water compartments heated by oil burners.

48.20

Figure 5-13.—Steamtable.

1538531

Operation.—When the steamtable is in use, steam condensation should drip to drain. If no condensation appears after 2 minutes of operation, turn off the steam valve and clean the strainer basket of the trap.

Do not overload food pans. An excessive amount of food makes it difficult to maintain the correct water compartment temperature, between 180°F and 200°F. If, on the other hand, water in the steamtable is allowed to become hotter than 200°F, the food will dry rapidly and continue cooking from the excess heat. You can correct this by adding more water to reduce the heat. Because food tastes best if served within 30 minutes (preferably within 15 minutes) after being placed in the steamtable, do not place food pans in the steamtable too early.

Care and Cleaning.—Wash pans in the pot sink by hand, using cleaning brushes, scouring powder, and hot soapy water; and rinse with hot fresh water at 180°F. Only fiber sponges should be used in cleaning pans of copper, copper-nickel, or corrosion-resistant steel.

After each meal, drain the steamtable, wash the tanks with hot soapy water, and rinse with very hot fresh water of at least 180°F. Wash the top and front of the steamtable to make it bright, clean, and sterile; then wipe it dry with a clean cloth.

Steamtables should be maintained in a sanitary, steamtight, and safe operating condition at all times. Metal parts should be kept free of corrosion by removing rust with solvents and by applying vegetable oil to bare spots.

Scales

The set of scale is one of the most important pieces of equipment you have. A scale will assist you in conserving food. When a recipe calls for a certain amount of food, you should weigh out that amount. Don't guess. This will make it possible to keep an accurate record of the subsistence on hand, and will aid you in preparing the correct amount of food.

Refrigerators

The Navy refrigerator used in the galley is similar to the one illustrated in figure 5-14. It consists of an insulated, stainless steel compartment, and rustproof, acid-resistant shelves. The refrigerator may be 16 or 30 cubic feet in size, and is designed for storing foods for short periods of time. Most refrigerators installed aboard ship have movable bars which fit in front of each shelf to keep the contents of the refrigerator from moving or falling out when the door is opened. At sea, food must be stowed in such a way that it will not move around when the ship rolls. To keep a refrigerator operating at top efficiency, three things are important:

KEEP IT CLEAN
DO NOT OVERLOAD IT
DEFROST IT REGULARLY AND PROPERLY

Washing the Refrigerator.—A refrigerator that is not thoroughly clean will quickly develop a bad odor, and the foods in it will spoil. Cleanliness retards the growth of mold and bacteria which often cause food poisoning. A refrigerator should be cleaned at least once a week and after each defrosting. Never hose down a refrigerator with running water. The fluid may seep into the insulation and cause permanent damage. The proper cleaning procedures are outlined as follows:

1. Wipe the gaskets around the door of the refrigerator to remove any oil or grease.
2. Wash the inside surfaces and food shelves with soap and warm water.
3. Rinse with a warm solution of baking soda, using 1 tablespoon of soda to 4 quarts of water.
4. Dry all surfaces thoroughly after flushing out the drain with hot water.
5. Clean the outside with warm water, rinse it, and dry it.

48.21

Figure 5-14.—Refrigerator.

8532

Avoidance of Overloading.—Never overload a refrigerator. An overloaded refrigerator is hard to clean because food odors spread more rapidly, and the cooling unit frosts more quickly. To prevent overloading, limit the amount of food you draw from bulk storage at any one time. When you draw food that must be kept in the refrigerator, don't ask for more than you can store.

Defrosting.—Defrost a refrigerator at appropriate intervals. The number of times that a refrigerator requires defrosting depends, of course, on the rate at which frost builds up on the cooling unit. Ice formations should never be one-half inch thick, because ice and frost act as insulators and reduce efficiency. Don't try to speed up the defrosting by scraping, chipping, or sticking the frost with an ice pick. Don't pour hot water on the cooling unit. Defrosting, however, may be speeded up by placing pans of hot water in the refrigerator.

MEAT CUTTING EQUIPMENT

The meat cutting room, commonly known as the butcher shop, is where meats, fish, and poultry, drawn from refrigerated storerooms, are prepared for cooking. The equipment normally found in this area consists of meat cutting blocks, meat grinding machines, power driven meat cutting saw, slicing machines, steak cubing machines, knives and other hand cutting tools, and hooks for hanging meats.

Meat Block

Meat blocks are made of hard maple. Depending on the tonnage displacement of a ship or whether she has a meat cutting room, they are furnished in the following sizes:

1. 24 by 24 by 16 on destroyers and ships under 2000 tons displacement
2. 30 by 30 by 16 on ships having a 2000 tons or more displacement
3. 35 by 50 by 16 on ships that have a meat cutting room

Care and Cleaning.—Clean the meat block (fig. 5-15) with a scraper and a wire brush after each use. Do not wash the cutting surfaces of the meat block. Moisture softens and expands the wood and weakens the glued joints which, when dried, contract and form cracks to collect food particles. Do not salt the block. Salt is not a bacteria destroying agent and may interfere with drying, or may conceal an unclean surface. Listed below are some of the rules that you should follow in order to keep the cutting surface of the meat block in good physical and sanitary condition.

1. Use a wide-bladed steel scraper and a wide-bristle wire brush to clean the cutting surface after each use. DO NOT use wash water on the cutting surface. Water should be used on the sides only.
2. Keep the cutting head of the block dry.
3. Turn the block regularly so that the cutting surface will wear down evenly. When the blocks become pitted, rough, and uneven, they are impossible to maintain in a satisfactory condition and should be trimmed by sanding or by other approved methods.
4. Use a special cutting board, and never the block when cleaning or cutting poultry, liver, hot meats, fish, fruits, and vegetables. Unhealthy organisms when present may contaminate the block, and the moisture and juices in these products make cleaning difficult.

Meat and Vegetable Chopper, Electric

The electric meat and vegetable chopper (fig. 5-16) is used to chop (or grind) all meats (cooked or raw) and to prepare bread crumbs from leftover bread and toast. The meat and vegetable chopper is portable and may be placed where most needed. It should be placed on a sturdy stand within easy reach of an electric outlet.

48.22

Figure 5-15.—Meat block.

48.23

Figure 5-16.—Meat and vegetable cutter.

Operation.—Usually a three-eights inch plate is used for grinding meat. The use of a three-sixteenths inch plate for such grinding puts too much pressure on the grinder. The coarser plates are for chopping vegetables. The cutting edge of the knife must go next to the plate. Never forcibly tighten the adjustment ring on the chopping end; tighten the adjustment ring on the chopping end; tighten it snugly. Excess pressure will wear the chopper parts.

Start the motor, then feed the material into the chopper. Turn the motor off when material is ground. Feed the material into the machine by means of a wooden stomper—NEVER WITH YOUR HANDS.

Care and Cleaning.—After meat has been chopped, take the grinder apart and wash each part thoroughly with soap and water, rinse with water 180°F, and allow to air dry. Do not allow food to dry on the surfaces of the chopper before washing it. A grinder can be a breeding place for bacteria which might cause food poisoning. Great care should be exercised in keeping the parts of the grinder free from contamination.

Knives and plates should be sharpened before they get dull, but do not attempt this yourself. The engineering department should be consulted. It is a good idea to keep the same knife and plate together as they wear to fit each other. Tie them together with a cord after use so they will not get mislaid.

Keep the motor dry. Don't grind juicy foods such as onions, for the juice is forced back into the gear housing, causing loss of oil and consequent wearing of gears.

If you are grinding foods such as crackers, grind a very small amount at a time or the machine will jam. When the chopper is hot, do not run raw meat through it. Remember that bits of bones can break worm gears and knives.

Motor-Operated Meat Saw

Electric sawing machines (fig. 5-17) are used mainly for cutting chilled, frozen, and smoked meats into steaks and chops. It is well to bear

28.137

Figure 5-17.—Electric meat cutter or sawing machine.

in mind that meat can be cut more uniformly by machine when there is still some frost in the boneless piece.

The saw is made to revolve by a mechanical arrangement of two wheels and an electric motor. The table on which the meat is laid is constructed so that you can cut the meat to any desired size. The saw blades themselves are five-eights inch wide and about 10 feet long.

Operating the Saw.—Before operating the saw, tighten the blade, using only one hand. Put only enough tension on it to keep it from skipping. Feed the meat through the straight, giving the blade a chance to cut. Use only sharp blades. Dull blades may heat up, twist, and break. DO NOT FORCE.

The electric meat cutter is a dangerous piece of equipment. A great deal of care is necessary to avoid injury when operating this machine. There are five safety precautions which should be observed whenever you operate the meat saw:

1. Before cutting meat, see that the right amount of tension is on the saw blade. There should be no flexibility whatsoever. The feel of the saw blade will be solid when the right amount of tension is applied.
2. Meat being sawed should be placed firmly against the sliding tray guide with enough pressure to maintain a uniform thickness of the slices.
3. Never use unnecessary force when cutting (sawing) meat. It is possible to break the blade and cause serious injury to yourself or others from flying pieces of metal.
4. Always make sure the guide is securely tightened after the adjustment for the thickness of the meat slices has been determined. Set the guide blade 2 inches above the meat.
5. Always keep your hands on the part of the meat which is most distant from the saw blade.

Care and Cleaning.—The revolving wheels have grease chambers. Pack them frequently. Keep the machine clean. Oil at least once a week. Always wash and sanitize machine properly after each use or after every 4 hours of continued use.

When washing, use hot soapy water, and rinse with water of 180°F. Do not drip water on the electric motor.

Meat Slicer

Meat slicing machines (fig. 5-18) are either hand operated or motor operated and are used for slicing hard or soft foods such as: roasts, cheese, bacon, luncheon meat, various kinds of sausages, and ham.

The machine has a carriage on which the meat is placed. A swiftly revolving disk knife slices the meat as the carriage is moved across the face of the revolving knife.

Operating the Meat Slicer.—To use the slicer, place the meat on the carriage and adjust the clamp to hold the meat firmly. This clamp also furnishes protection for your hand. Next, set the dial for the desired thickness of the slices. Then turn on the switch to make the disk knife

48.24

Figure 5-18.—A. Hand operated meat slicer, B. Electric meat slicing machine.

8535

disk knife revolve. Move the carriage back and forth with the hand lever. WARNING: KEEP YOUR HANDS AWAY FROM THE REVOLVING KNIFE.

The meat slicing machine can be a dangerous instrument if your aren't careful. Never use it when the blade guard is off. Don't leave the plug in the electrical socket when the slicer is not in use. Never put your hands under the guard, and don't operate the machine with wet hands.

Care and Cleaning.—The meat slicing machine should be cleaned thoroughly after use. This is done by removing all cutting and meat handling attachments. Before dismantling an electric machine, turn the switch off and unplug. Clean the slicer knife with a damp cloth, wipe it with a dry cloth, and cover the blade with a thin coating of salad oil to prevent rust. Never use a knife or other hard substance to scrape food particles from the slicer knife. Wash attachments with soap and hot water; rinse with water of 180°F and allow to air dry. Wash the machine with hot water and a stiff brush, taking care not to let any water get into the motor. (Do not use extremely hot water or steam to clean; too much heat may destroy lubricants.) Dry the machine thoroughly with a cloth after cleaning. Clean the counter top under the slicer. Reassemble the slicer immediately so that the bare knife will not be exposed. Replace all guards securely.

Cube Steak Machine

The cube steak machine is used to tenderize all sorts of tough meats. The machine is about 20 inches long and about 1 foot wide.

To operate, turn the motor on, insert the meat to be tenderized into the opening at the top of the machine. The meat will pass through two sets of revolving rollers (which contain many small blades) and will be made tender. If further tenderizing is required, insert the meat again after first giving it a one-quarter turn (90°).

Take the machine apart and clean after each use. Oil the parts often.

Knives, Cleavers, Meat Hooks, and Saws

Different sizes and shapes of tools are required for the many different ways of cutting meat. You must understand which knife or saw is used for each job and be sure that they are used for purposes for which they are intended. Be particularly careful with the bladed tools (knives and cleavers), for if they are improperly used their edges will be ruined. For example, you would never use the long thin-bladed knife that is designed for carving cooked meats to bone a roast. It is easier, quicker, and more efficient, to use the boning knife which has a stiff, narrow, short blade designed to cut close around bones. The knives with the long, wide blade are used to cut steaks and roasts before they are cooked.

To get the most use out of the knives in the galley, they must be sharp. A dull knife is a hazard and makes extra work for you. A boning knife has a comparatively narrow bevel and will stand more hard use than a steak knife which has a wide bevel and a thin edge. But no matter what tool you use, you can't do a good job unless it is sharp. The butcher's steel is used only to keep the edges of knives straight and not to sharpen them. Nor should you sharpen knives on a power or hand driven stone, since this removes the temper from the cutting edge. The best things to use for sharpening are a water stone and a carborundum oilstone. If you are careful to use the entire stone when sharpening tools the stone will not "hollow out" at any one point. Draw the full blade, from heel to tip, across the length of the stone and then turn the knife over and pull it back from the opposite end of the stone. This sharpens the knife evenly and smoothly and causes the stone to wear uniformly. Always clean the blade and handle thoroughly after sharpening.

In steeling there is a definite technique and definite types of steel to be used to true the edge. Never use a rough steel. A smooth steel is important in keeping the blade in perfect condition and maintaining a keen edge. The steel should have good magnetism in order to hold steel particles. The following is the easiest and most effective method of steeling a knife:

1. Hold the steel firmly in the left hand, thumb on top of the handle, with the point upward and slightly away from the body.
2. Place the heel of the blade against the side of the tip of the steel. The steel and the blade should meet at an angle of about 25°.
3. With a quick swinging motion bring the blade down across the steel toward the left hand. This should pass the entire edge lightly over the steel.
4. Bring the knife into position again but with the blade against the top side of the steel, and repeat the same motion of passing the blade over the steel.
5. Alternating the knife from side to side, a dozen strokes will true the edge. Steel your knives as often as necessary to keep their edges straight.

Keep your knives in good condition. Don't let tools with wooden handles stand in water. Hot water soaks into the wood causing it to expand. As the wood dries it shrinks. The handles become loose, the seams are enlarged, and a knife has been ruined. Besides, enlarged seams are unsanitary.

Never throw knives into a drawer with other cutlery or tools. It is a good idea to have a knife rack fastened to some convenient place in the galley or meat cutting shop. If you keep knives in a drawer, secure a wood strip to the bottom of the drawer with slots wide enough for the blade of a knife. This sort of rack keeps unused knives out of the way, and keeps the blades in good condition.

The meat cleaver should be used as little as possible. Unless it is kept very sharp and used properly, it will shatter the bone and drive bone splinters into the surrounding meat. These splinters can be dangerous as well as inconvenient.

The meat hook is a very great aid in boning meat. It saves time and enables the man doing the cutting to get a firm grip on a slippery piece of meat. It also lessens the risk of cutting fingers while boning a piece of meat.

For every meat saw in the galley, there should be at least three blades. If there are always two blades, properly set and sharpened, in addition to the one in use, considerable time and effort will be saved. When a blade loses its edge and set, it can be immediately replaced.

FOR YOUR SAFETY

To prevent accidents, use the safety devices on galley and meat cutting equipment as directed. Keep your equipment operative at all times. Report defects promptly, via chain of command, to the engineering department.

Of course, all manner of safety devices will not guard against food contamination. Complete cleanliness at all times is necessary. This requires, among other things, diligent care of equipment. When food preparation equipment and utensils are systematically and thoroughly cleaned after each use, the possibility of food contamination and bacterial growth is greatly reduced.

HELP PREVENT FIRE

There is always the danger of a fire breaking out on a fighting ship, with consequent damage to equipment as well as serious injury to personnel aboard. But fires do not occur in war alone. Many shipboard fires have occurred in peacetime. The best way to fight fires is to prevent them.

Warn your men about the kind of matches they bring aboard. Navy regulations say that safety matches ONLY are allowed. Require your men to observe the NO SMOKING sign in galley spaces. The sign is placed there for two reasons—one is for sanitation and the other is for fire prevention.

Clean the canopy over the ranges daily—especially when grilled meats have been prepared. Flames that may reach the canopy from the range won't spread if there is no grease and dirt for them to feed on. Have exhaust fans and ducts over the ranges cleaned at least once a week—oftener if necessary.

Keep galley spaces free of waste materials. Waste paper and rubbish should be deposited in proper receptacles and disposed of promptly.

Do not allow trash to accumulate around electric motors or machines, against steam pipes, or within 10 feet of any range, oven, or fryer, or in places where flammable products (grease) are used or stored.

Inspect regularly fire extinguishers located in galley spaces to see that they are in good working condition. Report those that are faulty to your superior, who will consult with the damage control division concerning their repair or replacement. It is too late to inspect fire extinguishers after a fire starts.

Your men should know how to give the alarm for fires and where firefighting equipment is located, how it is operated, and the principles behind its operation. They should know how to extinguish fires which may occur in galley spaces.

Fires are classified by the Navy into three general kinds, A, B, and C. Your military training courses describe these classes in detail and give appropriate methods for fighting each.

CHAPTER 6

NUTRITION AND MENU PLANNING

Because of the effect of food on morale and welfare, the preparation of adequate, balanced menus is very important. For this reason, the men who prepare the menus in the Navy must know the major nutritive constituents that a man needs to consume and the kinds and quantities of foods that must be served to enable each man to maintain good health. It is the responsibility of the menu planner to provide the right kinds of foods, and foods that men will enjoy eating. Unless eating is a pleasure, men may not eat enough of the foods that will keep them healthy.

As a Commissaryman, it is your job to learn which foods the crew on your ship like and which they do not like. Keep a weather eye out and record which foods bring requests for second helpings and which are rejected on the serving line, and listen to the comments of the crew.

In this chapter you will learn about the major nutrients that are found in the foods that your menus should offer. Knowing the important functions of these nutrients in maintaining health, you will have a better understanding of the need for planning menus that offer good combinations of certain key foods. You will not need to know the quantities of each nutrient furnished by individual foods. Nutritionists have simplified this task for you by grouping all foods according to the functions of the nutrients which they furnish. This chapter will also teach you how to use the "food groups plan" in developing nutritious menus for your crew.

FOOD CONTENT AND HEALTH

Over a period of time everyone should eat many different kinds of foods—not only because a change of menu is pleasant but because different foods make different contributions to health. Nutrients in food act in the body to supply (1) energy, (2) material for growth, (3) material to regulate body functions.

Calories

Food produces energy for the body as fuel produces energy to keep an engine running. The unit used to measure the energy produced by food is called a calorie, which is the amount of heat required to raise the temperature of 1 kilogram of water 1 centigrade or 1 pound of water 4° Fahrenheit. The number of calories a person needs depends upon the amount and kind of work he does, his age and weight, and the climate. The larger a person is, the more calories he will require. A large active boy of 15 may need as much as 5000 calories. An adult man weighing 154 pounds, who does very little physical work, as at a desk job, will need about 2500 calories a day. The same man doing moderately active physical work, as in performing active shipboard duties, will need about 3000 calories. If he is in boot training, he may need 4000 or more. Young men up to 20 years of age generally need about 3800 calories per day. Young sailors should get enough calories to show normal growth. Lack of calories will result in loss of weight, whereas too many calories will cause a person to gain weight.

The adjustment in calories required for tropical, temperate, or frigid areas is made by eating more or less food. No great changes in a GOOD diet need be made, except to increase or decrease the total quantity of food served. When the temperature is low and a sailor is exposed to the weather, his caloric requirements might easily be increased 25 percent or more.

Energy Foods

Proteins, fats, and carbohydrates are known as energy foods.

Proteins.—The most important nutritive elements required by man are proteins. They are body building materials. They build new tissues,

repair old tissues, and regenerate the blood. Certain proteins in the blood give us the means of developing resistance, and sometimes immunity, to disease. Milk, meats, fish, eggs, poultry, legumes (kidney beans, lima beans, lentils, peanuts), cereals, and vegetables are sources of protein and should be included in the daily meal pattern.

Fats.—The fats are the most concentrated source of energy. They are divided into two main groups, vegetable and animal fats. Butter, milk, cream, meat fats, oily or dark colored fish, and egg yolks belong to the animal fat group. The seed and vegetable oils are vegetable fats. Butter, oil, and shortening are readily recognized as fat foods. Fat however, is also blended, incorporated, or absorbed in other foods as for example the fat content of avocados, olives, and nuts. The addition of fat to a meal makes the meal more palatable and satisfying.

Carbohydrates.—The primary source of energy, the most readily digestible, the least expensive, and the most quickly available, are the carbohydrates. Cereals and cereal products, starchy vegetables, sugars, and fruits, are sources of carbohydrates.

Minerals

Minerals are the inorganic constituents of the diet and function in three ways. They are constituents of teeth and bones, giving rigidity and permanence to their structure; they are constituents of all soft tissues; and they influence the irritability of muscles and nerves. Although all minerals are important there are four which must be included daily.

Calcium.—The builder of bones and teeth is calcium. This mineral also contributes to the clotting of blood and regulates or controls normal heart rhythm. It is necessary for normal muscle contraction and nerve irritability. Sources of calcium are milk, cheese, clams, egg yolks, nuts, broccoli, cabbage, cauliflower, mustard greens, and turnip greens.

Milk is the best calcium source. It is almost impossible to supply the amounts of calcium needed unless milk in some form is used daily and cheese and other milk containing products are eaten frequently. Use 1 pint of fresh milk or its equivalent per person per day. If the diet is low in calcium, it is also likely to be low in riboflavin, the B_2 vitamin.

Phosphorus.—Also necessary for building bones and teeth is phosphorus. Milk, cheese, eggs, meat, legumes, nuts, whole grain cereals, and vegetables are good sources of this mineral.

Iron.—Iron is a component of bone and of hemoglobin, which gives the blood its color and which carries oxygen to the tissues. The best source of iron is liver. Liver is "meat deluxe" from the standpoint of nutrition. Other good sources of iron are lean meats, egg yolks, dried legumes, green leafy vegetables, enriched breads and cereals, and molasses.

Iodine.—The human body must have a small but steady amount of iodine to help the thyroid gland work properly. Seafoods are especially rich in this mineral and the salt the Navy buys has enough iodine in it to take care of some of the body's requirements.

Salt is needed by everyone. The need for salt and water is closely related. A person needs about 1 level teaspoon of salt per day and more when he perspires a great deal. The average intake of salt is from 2 to 3 teaspoons daily, which is enough for a person drinking up to about 4 quarts of water. A person who is not getting enough salt will become weak.

Water

Water is not a food but it can be far more important than food. A person can live several weeks without food but will die within a few days without water. About three-fourths of the body is made up of water. Much of this water is lost through perspiration and must be replaced frequently.

The average adult needs about two and one-half quarts of water daily. A large part of this amount is taken in with food, as a large percentage of most foods is water. When a man is working or during hot weather, he may need from 5 to 12 quarts of water daily. Water should be taken into the body as it is desired, since thirst usually serves as an adequate guide to intake, except during illness. When large amounts of water are taken daily, it may be desirable to take extra salt in the form of salt tablets.

Cellulose

Cellulose does not have the function of a food, which is to produce energy; cellulose aids in body activity. It is that woody, fibrous, or semifibrous substance contained in many foods, as for example bran or the soft hemicellulose which is found in fruits and vegetables. Cellulose has been

0528 8539

called the broom of the human body because by its own mass it shoves along food and body waste which otherwise might become stagnant in the intestines.

Vitamins

Vitamins occur naturally in foods in very minute quantities. They are odorless, tasteless, and invisible to the naked eye. They supply no heat to the body and no body-building elements, but they are indispensable to health and normal body functions.

Some vitamins can be stored in the human body; others cannot and must be supplied every day. Vitamins are usually grouped according to whether they are soluble in water or in fat. The water soluble vitamins, B and C, can be leached out of food that is cooked in water and will be lost unless the water is reserved for use in stews, soups, and sauces. These vitamins cannot be stored in the body and must be supplied every day. The fat soluble vitamins are A, D, E, and K.

B Vitamin Complex.—The B vitamin family has been broken down into at least ten parts. The whole group is called the vitamin B complex. Three vitamins of the complex are emphasized.

THIAMINE (B_1) promotes growth, creates a feeling of well-being, counteracts fatigue, and steadies the nerves. Good sources of thiamine are: lean meat (particularly pork), liver, whole-grain breads and cereals, enriched breads and cereals, legumes, peanuts, and milk.

RIBOFLAVIN (B_2) promotes growth and health. Generally it keeps the eyes, skin, and hair healthy. Good sources are: milk, liver, green leafy vegetables, whole-grain breads and cereals, and enriched breads and cereals.

NIACIN (Nicotinic acid) prevents a disease known as pellagra. It aids in digestion and the health of the skin. The best sources are liver and peanut butter. Lean meats, legumes (peas and beans), whole-grain breads and cereals, enriched breads and cereals.

Vitamin C.—The first vitamin separated from food was vitamin C. It is known as ascorbic acid. This nutrient helps to keep body tissues in good condition. Though not known at the time, a lack of this vitamin in the diet of seamen in the early days of the Navy caused the disease known as scurvy. In time, the Navy found that it could successfully fight the disease with lemon, lime, or orange juice. Tender and bleeding gums, hurting and swelling joints and weakened muscles are usually caused by a lack of vitamin C.

Vitamin C is necessary for the regulation of the heart muscle and muscle tone generally. It is also an important element in the cement substance which holds cells together and properly set in the body.

Since only a very limited amount of ascorbic acid (vitamin C) can be stored in the body, it is essential that you supply generous amounts in the daily diet. All of the familiar citrus fruits are excellent sources, as are various other fruits.

Other good sources of this vitamin are tomatoes, cantaloupes, raw green foods, fresh strawberries, and even potatoes if cooked in their jackets.

Vitamin A.—Milk, butter, cream, cheese, liver, egg yolk, leafy green and yellow vegetables, yellow fruits, cod liver oils, and other fish liver oils contain vitamin A.

Vitamins help to protect the body against infection and vitamin A's guard duty is to help keep the skin and the lining of the nose, mouth, eyes, and inner organs in good condition. A lack of vitamin A may cause the mucuous membranes around the eyes to become diseased, and a shortage of this vitamin may cause injury to the respiratory, digestive, or excretory systems.

Shortage of vitamin A in the diet may cause night blindness. Experiments with diets of high vitamin A content for aviators and automobile drivers have proved that the increased amount of vitamin A reduces accidents at night. Industry has also found similar results with workers. As you know, the Navy must constantly be on the alert for night blindness in personnel, particularly those required to stand watch duty. Many naval battles of the past have been started at night because the enemy desired to take advantage of the light conditions and the greater difficulties with vision at that time of day.

Vitamin D.—The direct rays of the sun or suitable ultraviolet rays change substance in the skin to vitamin D, so it is known as the "sunshine vitamin." The exact needs of adults for this vitamin are not known, but a certain amount is necessary for continued maintenance of the structure of the body. Bones are weakened by a lack of vitamin D.

Significant amounts of vitamin D are found in only a few natural foods. Fish liver oils, such as cod, are among the richest sources. Salmon, mackerel, tuna, sardines, beef liver, lamb and pork liver, eggs, butter, cream, and whole milk furnish small amounts.

Vitamin E.—Essential to growth, vitamin E is found in meat, milk, butter, grains, and vegetables.

Vitamin K.—A key element in the clotting of blood is vitamin K. Spinach and leafy vegetables such as cauliflower and turnip greens are good sources of this vitamin.

Figure 6-1 presents summary information about vitamins. This information will be valuable to you in making and analyzing menus, and also in conserving vitamins during cooking. The "stability," as used in the illustration, refers to the ability of the various substances to withstand destruction under the conditions mentioned.

THE NAVY RATION LAW

The first Navy Ration Law is found in an Act of Congress passed in 1794 which provided for a daily fixed allowance of food items for each day of the week. A typical day's ration was one pound of hard bread, one and one-half pounds of salt beef and one-half pint of rice. Included with this ration was a half-pint of distilled spirits or one quart of beer.

In 1842 the fixed allowance for each day of the week, as provided for in the 1794 Ration Law, was discarded in favor of a more flexible allowance of specified items and permitted substitution.

In 1862, the spirits ration was discontinued. This action was compensated for by a five-cents-a-day pay raise. Fresh meat and dried vegetables and fruit were added to the ration which by that time already included coffee, tea, and sugar. By 1902, the management of the general messes had been assigned to the supply officers of the Navy and it was in this year that the first Navy Cook Book was published.

Chemical Name	A	C	D	Vitamin B Complex		
	Carotene	Ascorbic Acid	Calciferol	Thiamine (B_1)	Riboflavin (B_2)	Niacin
Important food sources	Liver Egg yolk Vegetables Green Yellow Butter Cream Fish-liver oil	Citrus fruits Cabbage Tomatoes Cantaloupes Strawberries Potatoes in jackets	Fish-liver oil Butter Egg yolk Liver	Pork Liver Organ meats Nuts Legumes Whole wheat Whole grains	Liver Meats Eggs Milk Enriched bread Vegetables Green Leafy	Meat Fish Poultry Liver Green peas
Stability: cooking drying light	Gradual destruction by exposure to heat and drying at high temperature.	Unstable to heat and oxidation, except in acids. Destroyed by drying and aging.	Stable to heating, aging and storing.	Unstable to heat and oxidation.	Stable to heat in cooking, to acids and oxidation. Unstable to light.	Stable to heat, light and oxidation, acids and alkalis.
Lack of this vitamin causes	Night blindness; glare blindness Rough, dry skin Dry mucous membrane	Scurvy Sore mouth Stiff joints Sore and bleeding gums Weak-walled capillaries	Rickets Soft bones Bowed legs Poor teeth Skeletal deformities	Beriberi (man) Poor appetite Constipation Fatigue	Eye sensitivity Cataract	Pellagra

48.24.0

Figure 6-1.—Summary of information on vitamins.

One hundred years after the establishment of the first Navy Ration Law, the great improvements are illustrated by the following:

SEA ROUTINE BILL OF FARE,
U.S.S PORTSMOUTH, 1894

	Breakfast	Dinner	Supper
Monday	Beans	Bean soup	Canned mutton
Wednesday	Coffee	Salt port*	Dried apples
Saturday	Hardtack Black molasses	Hardtack Coffee	Tea Hardtack

*Wednesdays at dinner yellow pea soup was served for a change.

Tuesday	Cracker hash Coffee Hardtack	Salt horse Corn pone Hardtack Coffee	Scouse Molasses Hardtack Tea
Thursday	Prunes Hardtack Molasses Coffee	Plum duff Salt horse Hardtack Coffee Molasses	Cracker hash Tea Hardtack Molasses
Friday	Cracker hash Hardtack Coffee Molasses	Salt horse Corn bread Hardtack Molasses Coffee	Scouse Hardtack Molasses Tea
Sunday	Cooked dried apples Hardtack Coffee Molasses	Plum duff Salt horse Coffee Hardtack Molasses	Cracker mutton Hash Tea Hardtack Molasses

The molasses was of the old-fashioned black strap kind, thick and heavy. The hardtack was really HARD. The coffee was weak enough to prevent the crew from getting nervous. (The bottom of the coffee pot was always to be seen when it was full.) The salt horse and pork came in large barrels and when opened (to leeward) the smell was hot. It generally was put in small cargo nets and towed overboard to get the rock salt and smell out of it. (Sharks never disturbed it.) On bean and pea soup days, enough was generally made to have enough for soaking hardtack to make scouse. When in port the crew generally fared pretty well, as they could get fresh food and vegetables but never cake and rarely butter. Meals generally consisted of stews, soups, meats, and potatoes. Fruit had to be bought from bumboats by the crew as it was rarely served in the mess. The ration was approximately $9 a month per man. The sea ration was all they had on the trip from Newport, R.I., to Queenstown, Ireland, 16 days; and 42 days from Funchal, Madeira to Newport; fresh vegetables and meats could not be carried beyond 2 or 3 days.

In 1933, the present Navy Ration Law became effective. It increased the allowance of vegetables, milk, and fruit while decreasing the allowance of meat. This ration law has remained unchanged to the present time except for the addition of vegetables and fruit juices and enrichment of flour with vitamin B_1, niacin, iron and enriched yeast.

The present Navy Ration Law is authorized by the Congressional Act of 2 March 1933 (47 stat. 1423), as amended (34 U.S. Code 902a). The Navy Ration is a quantity allowance of food. Each person, so entitled, may be served the following quantities of food each day:

- 8 ounces biscuit, or 12 ounces soft bread, or 12 ounces flour
- 12 ounces preserved meat, or 14 ounces salt or smoked meat, or 20 ounces fresh meat or fresh fish or poultry
- 12 ounces dried vegetables, or 18 ounces canned vegetables, or 44 ounces fresh vegetables
- 4 ounces dried fruit, or 10 ounces canned fruit, or 6 ounces preserved fruit, or 16 ounces fresh fruit, or 6 ounces canned fruit or vegetable juices or 1 ounce of powdered fruit juices or $^{6}/_{10}$ of an ounce of concentrated fruit juices
- 2 ounces cocoa, or 2 ounces coffee or $^{1}/_{2}$ ounce tea
- 4 ounces evaporated milk, or 1 ounce powdered milk, or $^{1}/_{2}$ pint fresh milk
- 1.6 ounces butter
- 1.6 ounces cereals, or rice, or starch foods
- $^{1}/_{2}$ ounce cheese
- 1.2 eggs
- 1.6 ounces lard or lard substitutes
- $^{2}/_{5}$ gill oils, or sauces, or vinegar
- 5 ounces sugar
- Baking powder, and soda, flavoring extracts, mustard, pepper, pickles, salt, sirup, spices, and yeast as required.

1078 8642

DAILY FOOD REQUIREMENTS

The food we eat each day must supply the proteins, minerals, vitamins, carbohydrates, and fats needed to maintain the body in a healthy state. Most foods contain more than one nutrient, but no single food furnishes all the nutrients in proper quantities. To make it easier to plan menus that will have adequate quantities of all the necessary nutrients, foods are grouped together according to the substances they provide.

The BASIC FOUR foods, as outlined in the plan which follows, designate the minimum number of servings of each group which meet the needs of the body and form the foundation for a good diet (see fig. 6-2). To round out meals and to satisfy the appetite, more of these foods are used, and foods not specifically mentioned may be used—butter, other fats, oils, sugars, and unenriched grain products. These other foods are frequently combined with suggested foods in mixed dishes, baked goods, desserts, and other recipe dishes. Fats, oils, and sugars, are also added to many foods during preparation, and when served, enhance flavor and improve appetite appeal.

Each of the food groups listed has a special job to do in helping toward an adequate diet. In the number of servings specified and with the choices indicated, these foods grouped together furnish all, or a major share, of the calcium, protein, iron, vitamins A and C, and the B vitamins recommended. Other minerals and vitamins as well as fats and carbohydrates are also provided.

The Basic Four

The Basic Four groups are:

- Group I —Milk
- Group II —Meat
- Group III—Vegetables and fruit
- Group IV—Bread-cereals

Three of the four food groups furnish one key food value each plus additional value.

The milk in Group I furnishes calcium plus proteins and vitamins. The meat in Group II furnishes protein plus minerals and vitamins. The vegetables and fruits in Group III furnish vitamins A and C and some of most other food values. The fourth group, bread-cereals, furnishes many of the B vitamins plus protein, iron, and calories. Additional amounts of food values and needed calories are supplied by other foods.

Group I: Milk.—Milk is used in many forms—fluid, whole, evaporated, skim, dry, buttermilk, and all types of cheese (cottage, cream, cheddar-type, natural or processed). Two or more cups of milk a day are the basic requirement. Cheese and ice cream may replace part of the milk. The amount of milk is figured on the basis of calcium content. Common portions of various kinds of cheese and ice cream, and their milk equivalents in calcium are:

1 inch cube cheddar type cheese	= $^2/_3$ cup of milk
$^1/_2$ cup cottage cheese	= $^1/_3$ cup of milk
2 tablespoons cream	= 1 tablespoon of milk
$^1/_2$ cup ice cream	= $^1/_4$ cup of milk

Group II: Meat.—Included in the meat group are beef, pork, veal, lamb, rabbit, and meat products, fish, shellfish, eggs, and as alternates, dried beans, peas, nuts, peanuts and peanut butter. Two or more servings are required every day. You may count as a serving, 2 to 3 ounces of lean cooked meat, poultry or fish, or 2 eggs or 1 cup of cooked dry beans or 4 tablespoons of peanut butter.

Group III: Vegetables and Fruits.—Included in this group are all vegetables and fruits. The Basic Four guide emphasizes those that are valuable as sources of vitamin C and vitamin A. Sources of vitamin C are divided into groups, Good Sources and Fair Sources.

Good Sources	Fair Sources
Grapefruit or grapefruit juice	Honeydew melon
Orange or orange juice	Tangerines
Cantaloupes	Watermelon
Mangoes	Asparagus
Papaya	Brussels sprouts
Raw strawberries	Raw cabbage
Broccoli	Collards
Green peppers	Garden cress
Sweet red peppers	Kale
	Kohlrabi
	Mustard greens
	Potatoes and sweet potatoes cooked in jacket
	Spinach
	Tomatoes or tomato juice
	Turnip greens

Sources of vitamin A are dark-green and deep-yellow vegetables and a few fruits, namely:

Apricots	Kale
Broccoli	Mangoes
Cantaloupes	Pumpkin
Carrots	Spinach
Chard	Sweet potatoes
Collards	Turnip greens and other deep green leaves
Cress	Winter squash

FOOD FOR FITNESS

A Daily Food Guide

MILK GROUP

SOME MILK FOR EVERYONE

CHILDREN UNDER 9 . 2 TO 3 CUPS
CHILDREN 9 TO 12 . . 3 OR MORE CUPS
TEENAGERS. . . . . 4 OR MORE CUPS
ADULTS. . . . . 2 OR MORE CUPS

MEAT GROUP

2 OR MORE SERVINGS

BEEF, VEAL, PORK, LAMB, POULTRY, FISH, EGGS

AS ALTERNATES–
DRY BEANS, DRY PEAS, NUTS

VEGETABLE FRUIT GROUP

4 OR MORE SERVINGS

INCLUDE–
A CITRUS FRUIT OR OTHER FRUIT OR VEGETABLE IMPORTANT FOR VITAMIN C
A DARK-GREEN OR DEEP-YELLOW VEGETABLE FOR VITAMIN A–AT LEAST EVERY OTHER DAY
OTHER VEGETABLES AND FRUITS, INCLUDING POTATOES

BREAD CEREAL GROUP

4 OR MORE SERVINGS

WHOLE GRAIN, ENRICHED, OR RESTORED

PLUS OTHER FOODS AS NEEDED TO COMPLETE MEALS AND TO PROVIDE ADDITIONAL FOOD ENERGY AND OTHER FOOD VALUES

48.25

Figure 6-2.—Basic Four Food Groups.

88 8544

Plan to include 4 or more servings every day including:

1 serving of a good source of vitamin C or 2 servings of a fair source

1 serving, at least every other day, of a good source of vitamin A.

The remaining 1 to 3 or more servings may be any vegetable or fruit, including those that are valuable for vitamin C and vitamin A.

Group IV: Bread and Cereal.—Foods included in this group are breads and cereals that are whole grained, enriched, or restored. Specifically, this group includes: breads, cooked cereals, ready-to-eat cereals, cornmeal, crackers, flour, grits, macaroni, spaghetti, noodles, rice, rolled oats, and quick breads and other baked goods if made with whole grain or enriched flour.

Plan to include 4 servings or more each day, and if no cereals are to be served, allow an extra serving of bread or baked goods which will make at least 5 servings for this group daily.

You may count as a serving, 1 slice of bread or 1 package of ready-to-eat cereal or $^1/_2$ to $^3/_4$ cup cooked cereal, cornmeal, grits, macaroni, noodles, rice, or spaghetti.

MENU PLANNING

As you advance, you will be assigned more responsibility for planning menus for the general mess. A well-planned menu is the first step in assisting the cook in preparing and serving meals which, in addition to being well balanced and nutritious, also appeal to the appetite. Foods appeal to the appetite through color, flavor, texture, and variety of form. Good tasty meals are taken for granted by the men and they will expect to get them.

Any cook may on occasion serve a meal that isn't popular but the good cook will determine what is wrong, and not make the same mistake again. Careful planning will help eliminate unpopular meals.

Planning Attractive Menus

Color contrasts are important. Too many foods of the same color in any one meal make that meal uninteresting. Salads made of fresh vegetables, fruit, or a combination of fruits and vegetables, provide good color contrast. Carrots or yams will provide good color contrast with a meat course and a green vegetable or salad, but avoid carrots and yams together. Serve cauliflower when other dishes are colorful, not with creamed chicken and mashed potatoes.

Flavor is also important and again contrasts are necessary. Foods that have contrasting flavor tempt the appetite. The use of sour or sweet pickles, condiments (mustard, catsup, chile sauce, etc.), spices, and seasonings helps to provide these contrasts. Flavor and aroma are so closely linked in our minds that if food smells good it also tastes good. The aroma of meat cooking, eggs frying or coffee brewing puts men in the right mood for eating. Do everything you can to make the odor of the food agreeable.

Contrasts in the form and texture of food make it more appetizing. For instance, with creamed sea food over rice, you might serve broccoli or green beans, providing contrast in texture, form, and color.

Variety is the spice of life, and very important in cooking. Anyone gets tired of eating the same kind of food over and over no matter how good that food tasted the first time. Try to avoid repeating a menu too frequently.

The season of the year also affects the menu, both in the type of food available and the best types of food to eat.

Using Ration-Dense Foods

Another consideration for the menu planner is the use of ration-dense foods. These are concentrated, prefabricated, compressed, precooked, and frozen foods from which waste and replaceable substance have been removed. Their work-saving, time-saving features are important assets when developing a menu.

Standard Menu Format

In planning a menu you should use the following standard format:

Breakfast	Dinner and Supper
Fruit	Soup
Cereal	Meat
Milk	Gravy, sauce, or condiments
Eggs or substitute	Potatoes or substitute
Sweet rolls and/or toast	Other cooked vegetables
Butter—jam or jelly	Salad or relishes
Coffee	Bread or rolls
	Butter
	Dessert
	Beverages

You will note that there is a standard sequence in which food items are listed at each meal.

STEP 7.
SOUPS & BEVERAGES

The Menu Draft

The menu draft form (see fig. 6-3) allows for a 7-day menu plan. It is better management, however, to plan menus for 2 weeks or more.

There is no single way and no definite sequence of steps to be followed by all menu planners. Most meals are planned around the meat as the main dish, and other food items are selected to go along with the main dish. The step method listed below is suggested. Each step is followed across the draft form horizontally.

STEP 1. Main dishes, gravies, sauces, and accompaniments
STEP 2. Potatoes, potato substitutes, and vegetables
STEP 3. Salads and dressings
STEP 4. Breakfast fruits and cereals
STEP 5. Desserts
STEP 6. Breads, spreads, and breakfast pastries
STEP 7. Soups and beverages

At this point you will recognize that the daily menu is a plan for the day. With this in mind, the drafted menu should be reviewed and analyzed, asking these questions: Did you use authorized and available subsistence items? Did you include the proper amounts of Basic Four foods each day? Can the items be prepared using the equipment in your galley and the number of men on watch to do the work? Can all the foods be ready at the right time? What foods require last minute preparation? Does any meal show items that require a hot and a slow oven at the same time? Is the menu attractive in color, flavor, and texture contrast? Is there sufficient variation from previous menus to avoid monotony?

When you have decided what foods you will serve, list opposite each item the recipe card number in the Navy-Marine Corps Recipe Service (or your own locally approved recipe). BuSandA Manual requires that you do this, and you will find that the listing helps in several ways. Chiefly, it makes clear to everyone concerned exactly what you plan to serve and thus avoids misunderstandings. From these listings the jack-of-the-dust can conveniently assemble the recipe cards which will be his guide in planning breakouts.

When you understand the "hows" and "whys" involved in planning the menu, you will appreciate the important role that it plays in promoting efficient mess operations. Food Operations Reference Manual, NavSandA Publication 421, discusses in detail all aspects of writing menus. The publication Navy Food Service, which is mailed to all food service officers each month, includes a suggested menu. Both of these publications should be carefully studied by every Commissaryman. Navy Food Service, in addition to the suggested menu, publishes pertinent instructive information and guides concerning subsistence items, food preparation, and serving hints.

CHAPTER 7

EXPENDITURE OF SUBSISTENCE ITEMS

In chapter 4 of this text you learned about storage and care of subsistence items. Now let us see how all these subsistence items are moved from their storage spaces to the galley where they are used.

The nonperishable items are issued by the Storekeeper or a Commissaryman in charge of the bulk storeroom to the jack-of-the-dust in charge of the issueroom. The jack-of-the-dust then issues the nonperishable items to the galley as needed.

The senior butcher prepares and issues the meats to the galley directly from the cold storage compartment. The spud coxswain supplies the galley with fresh and frozen fruits and vegetables. Figure 7-1 shows how this system operates. On larger ships and stations a Commissaryman or Storekeeper is in charge of the refrigerated spaces and issues subsistence items to the butcher shop, galley, vegetable preparation room, and bake shop as required.

HOW MUCH SHALL BE ORDERED?

How does the cook in the galley know what and how much to order? The kind of subsistence items ordered is based on the menu for the day, as set up in the General Mess Menu (S. and A. Form 1080).

48.27

Figure 7-1.—How subsistence items get to the galley.

The amount ordered depends on the number of men to be fed in the general mess. This number is estimated from the Personnel Recapitulation and Mess Ration Credit (S. and A. Form 27), submitted by the executive officer or personnel officer. (See fig. 7-2.)

Suppose the menu calls for Salisbury steaks. First look up the recipe for Salisbury steak in your Navy-Marine Corps Recipe Service. Recipe card J-45 states that you need 29 pounds of ground beef to feed 100 men. Suppose you're feeding 60 men. You need $^{60}/_{100}$ or six-tenths of 29 pounds of ground beef.

$$^{6}/_{10} \times 29 = {}^{174}/_{10} = 17.4 \text{ lbs}$$

Ration of your mess to 100 men

Pounds needed per 100 men

Pounds needed for your mess

Suppose 89 men eat in your general mess. What then? When the number cannot be changed to a simple, easy to handle fraction, do the problem this way: multiply the number of men to be fed by the recipe AMOUNT.

$$89 \times 29 = 2581$$

Number of men

Pounds needed per 100 men

Pounds needed, uncorrected as to decimal place

Then place a decimal point in front of the second number from the right and you get 25.81. You make it 26 pounds of ground beef on your order.

If you have difficulty in working out the amounts that are needed, you will do well to get a copy

of the Navy Training Course, Mathematics, volume 1, NavPers 10069-B, and review those sections that deal with fractions and decimals.

Another Example

The menu calls for grilled steaks or chops. There are 1778 men to be fed. How much meat, boneless (steaks or chops), is needed? According to the recipe card J-5, 47 pounds are needed for 100 men. So, you multiply:

1778 x 47 = 83,566

Number of men

Number of pounds needed for 100 men

Pounds needed, uncorrected as to decimal place

Now place a decimal point in front of the second number from the right, and you get 835.66. You should request 836 pounds of steaks or chops.

ISSUEROOM RECORDS

The general mess issueroom is maintained as a current supply storeroom containing small lots of subsistence items drawn from the bulk storeroom and/or partial (broken) cases of subsistence items for issue to meet the demands of the menu.

A record kept on a stock tally card system may be used to account for stocks on hand in the issueroom.

If you are serving as jack-of-the-dust, you can use these stock tally cards to keep tab on the stock available for daily galley issues, to record breakouts of subsistence items cleared through the issueroom, and to aid in the quarterly inventory. It is recommended that a permanent, individual set of stock tally cards be maintained for all subsistence items in each bulk storeroom.

When you place requisitions for subsistence items, you should make reference to the Federal Stock Numbers listed in the Federal Supply Catalog, Federal Supply Classification Group 89, Subsistence. Subsistence items are usually requisitioned from Navy Supply Centers, depots, and other Navy ships on a DOD Single Line Item Requisition System Document (Manual) (DD Form 1348). See figure 7-3. Some commands may require the use of a Requisition and Invoice/Shipping Document (DD Form 1149) for the requisitioning of perishable subsistence items.

A Stock Tally is shown in figure 7-4. Notice that the description of the article is complete. After the supply officer establishes HIGH and LOW limits for an item of stock, enter the limits on the stock tally card. Thereafter, check these limits frequently to determine when replenishment action is necessary. In making your decision about replenishment action, take into consideration LEAD TIME—the probable time BETWEEN THE

STOCK TALLY—NAV. S. AND A. FORM 209 (REV. 6-51)

Figure 7-4.—Stock Tally. 24.22

DATE OF ORDER and the DATE OF RECEIPT of material. If you do not do this, occasionally you will come up short on essential subsistence items. When subsistence items are received, indicate the amount received in the "received" column and add this amount to the previous balance to get the new balance. When subsistence items are issued, indicate the amount issued in the "issued" column and subtract this amount from the last balance to get the new balance. Receipts and expenditures should be posted immediately as they occur.

TYPES OF EXPENDITURES

Expenditures of subsistence items normally are made by breakouts, issues to the general mess, transfers, sales to authorized messes, or surveys. The following paragraphs give a general idea how this is accomplished.

Breakouts

Breakouts of subsistence items should not be made from the bulk storeroom, issueroom, or the consolidated bulk-and-issue storeroom without prior written approval of the food service officer or other person designated by the food service officer.

Requests for breakouts from the above spaces are made on a Request for Issue or Turn-in (DD Form 1150) or a Subsistence Report (S. and A. Form 1059-1), prepared in triplicate. (See fig. 7-5.) The accomplished form must be signed by both the bulk storeroom or consolidated bulk and issueroom Storekeeper or the person to whom the issues are made.

After the form has been properly signed, distribute the original and two copies as follows:

1. Return the original to the supply office, where it is retained under lock and key by the food service officer.
2. Retain the duplicate in the bulk storeroom or consolidated bulk and issueroom for posting to the appropriate Stock Tally (S. and A. Form 209).
3. The triplicate is retained by the issueroom Storekeeper (jack-of-the-dust) for posting to the appropriate S. and A. Form 209, or it is retained by the senior Commissaryman for reporting issues to the general mess.

Issues to the General Mess

Issues to the general mess are authorized by the food service officer or other person designated to perform such duties. All of the issues should be supervised by the senior Commissaryman or another enlisted person designated to perform such duties. Every morning the senior Commissaryman submits a Subsistence Report (S. and A. Form 1059-1) to the food service officer, reporting all issues to the general mess for the previous day.

Issues to the general mess are posted to the:

1. Issueroom Stock Tally (S. and A. Form 209) by the jack-of-the-dust as transactions occur.
2. Subsistence Ledger (S. and A. Form 335) by the office Storekeeper as transactions occur.
3. Record of Receipts and Expenditures (S. and A. Form 367) by the office Storekeeper at the end of the accounting period only.
4. General Mess Control Record (S. and A. Form 338). Using a fixed price list established by the Navy Subsistence Office, the office

8554

Storekeeper posts the total value of issues to the general mess, less the value of galley-produced bakery products sold to private messes.

Familiarize yourself with the S. and A. Form 338. It provides an accurate, cumulative account of the financial status of the general mess. Overissues are immediately visible and can usually be eliminated prior to the end of the accounting period. (See fig. 7-6.)

The S. and A. Form 338 is posted as follows:

Column	Explanation of Entry
1	Day of the month.
2	Number of daily rations allowed. The number of daily rations allowed is taken from the effective Personnel Recapitulation and Mess Ration Credit (NavSandA Form 27).
3	Cumulative total of column 2 for accounting period.
4	Value of subsistence items issued to the general mess. This figure is posted daily from the subsistence reports reflecting actual issues to the general mess. DO NOT include dairy products and the products and the value of sales of galley produced bakery products.
5	Cumulative totals of column 4. This figure reflects the cumulative value of subsistence items issued to the general mess for the accounting period.
6	This is the quotient of column 5 divided by column 3. Here is where you can determine the financial condition of the general mess. Column 6 is another cumulative figure since it reflects the average ration cost as of the current posting. If, for example, your ration allowance is $1.07 and column 6 in figure 7-6 shows an average ration cost of $1.0472 on the 31st of the month, then the general mess is underissued by

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Column	Explanation of Entry
6—Continued	
	$.0228 per ration. Now multiply $.0228 by 20,625 (total allowed rations) and you find that the general mess is $470.25 underissued.
7	Column 7 shows the daily monetary allowance. Assuming that the ration allowance is $1.07, multiply $1.07 by column 2. By comparing column 7 with column 4, you can determine the amount of overissue or underissue for any one particular day.
8	This column is the cumulative monetary allowance. Compare column 8 with column 5 and you can determine the net cumulative overissue or underissue.

Notice that while the NavSandA Form 338 is designed to cover only a 31-day period, it is maintained over a quarterly period. All cumulative figures, therefore, run through the end of the quarter and not monthly as the form may imply.

Transfers

Transfers are those expenditure transactions by which the custody of subsistence items passes from one accountable officer to another accountable officer.

Authority to break out subsistence items for transfer to other supply officers from the bulk or consolidated bulk and issue storerooms is a properly approved DOD Single Line Item Requisition System Document (Manual) DD Form 1348, or Requisition and Invoice/Shipping Document (DD Form 1149). Such expenditures must be posted to the Stock Records: S. and A. Form 209 by the bulk storeroom Storekeeper or the jack-of-the-dust, as appropriate; Subsistence Ledger (S. and A. Form 335) by the office Storekeeper; and Record of Receipts and Expenditure (S. and A. Form 367) by the office Storekeeper.

Sales to Authorized Messes

Subsistence items may be sold to private messes when, in the opinion of the food service officer, the sale will not unduly deplete the quantity available for issue to the general mess.

Subsistence items may be sold to the following messes:

1. Flag mess
2. Cabin mess
3. Wardroom mess
4. Warrant officers' mess
5. Chief petty officers' mess

Sales Procedure.—The authorized representative of the private mess prepares, in quadruplicate, a Request for Issue or Turn-In (DD Form 1150) or a Subsistence Report (S. and A. Form 1059-1), as applicable.

All requisitions should bear a serial number. A separate block of numbers may be assigned to each mess so that all requisitions from a mess will be numbered consecutively. The various blocks will comprise one numbering series for the entire ship.

The breakout form must be approved by the mess treasurer or his authorized representative who retains the No. 4 copy. If a person other than the mess treasurer is authorized to approve requests for breakouts, such authority is furnished the food service officer in writing.

After the breakout form has been approved by the food service officer or his authorized representative, the office Storekeeper prices each item with the last receipt unit price at the time of issue. This unit price is used to bill the private mess. Upon receipt of the subsistence items, the mess representative signs the original and two copies of the DD Form 1150 or the S. and A. Form 1059-1, as applicable, which are then distributed as follows:

1. The signed original is returned to the supply officer where it is retained under lock and key by the food service officer until the monthly billing.
2. The signed duplicate is returned to the mess treasurer.
3. The signed triplicate is used for posting to the Stock Tally (S. and A. Form 209) and forwarded to the supply office for posting to the Subsistence Ledger (S. and A. Form 335) and then retained for the record.

Sale of Galley-Produced Bakery Products.—A separate issue document, DD Form 1150, is used by messes to procure galley-produced bakery products from the general mess.

The DD Form 1150 is submitted in triplicate, listing the items and quantities required, and must be approved by the mess treasurer or his designated representative prior to issue approval by the officer accountable for the general mess.

The issue document is priced in the supply or food service office by the office Storekeeper from a price list furnished by the Navy Subsistence Office (see fig. 7-7).

The cost of galley-produced bakery products, which do not appear in the price list, is established

8556 8555

ITEM	UNIT OF ISSUE	PRICE
Baking powder biscuits	Dozen	$ .09
Bread	Pound	.06
Cake, 3-layer, 10" diameter, iced	Each	.63
Cake, 2-layer, 10" diameter, iced	Each	.44
Cake, 18" x 26" sheet, iced	Each	1.40
Cake, 18" x 26" sheet, iced (cut 50 servings per sheet)	Serving	.03
Cookies	Dozen	.15
Doughnuts, iced	Dozen	.21
Pies, cream, with whipped cream	Each	.38
Pies, fruit, two crust	Each	.42
Rolls and sandwich buns	Dozen	.10
Rolls, sweet, iced	Dozen	.21

48.30

Figure 7-7.—Price list of galley-produced bakery products.

at the local level, using the last receipt invoice price for the basic ingredients.

The distribution of the original and two copies of the DD Form 1150 is the same as for ordinary sales to messes.

Sale of Meat.—As far as possible, fresh meats should be sold in the units in which they are received aboard—beef in quarters or in complete units; veal, semiboneless; and mutton in carcasses. A complete unit is a group of cuts which includes all regular cuts from a carcass. When it is necessary to sell meat in market and small cuts, each special mess should be charged with the appropriate percent of the average cost price. This percent is found in Volumes III, IV, and VIII of the BuSandA Manual.

The following percentages of the issue price apply to sales of portion-cut beef, boneless, frozen, 6-way, effective when this text was written:

	Percent of Unit	Percent of Unit Price
Portion-cut grill steaks	13.50	170
Oven roasts	16.50	130
Portion-cut swiss steaks	11.00	120
Pot roasts	15.00	100
Diced	10.00	90
Ground	34.00	60

For example, if the last receipt unit price of portion-cut beef, boneless, frozen, 6-way is $0.59 per pound, sale of grill steaks is made at 170 percent of $0.59 (1.70 x $0.59) or $1.003 per pound. Rounded off to the nearest cent, the price is $1. If diced beef is sold, the unit price is 90 percent of $0.59 (.90 x $0.59) or $0.5310. Rounded off to the nearest cent, the price is $0.53 per pound.

Payment for Sales to Private Messes.—Monthly, a money value DD Form 1149 is prepared by the food service officer for each mess covering sales of subsistence items. The DD Form 1149 is submitted to the cognizant mess treasurer not later than the twelfth day of the month following the period covered. The applicable issue documents should be listed by document number (fig. 7-8) on the DD Form 1149. You will also notice the money value of galley-produced bakery products is shown separately, listing the appropriate issue documents.

The food service officer collects from the mess treasurer the total amount shown on the invoice. This money is later deposited with the disbursing officer. The disbursing officer acknowledges receipt of the funds on the original invoice and other required copies. The original of the DD Form 1149 is retained by the food service officer for submission with the appropriate returns.

8556

Surveys

When you come upon spoiled subsistence items or items about which you are doubtful, put them aside immediately so that they will not be used. It may be advisable to tag them. Then notify your food service officer via the senior Commissaryman. If he agrees that the subsistence items are not suitable, he will see that a request for "survey" is made.

What Is a Survey?—In Navy Regulations and the BuSandA Manuals, a survey is regarded as a means of establishing the reason for deterioration or loss of Government property. In the supply department, a survey is most frequently used as a means of accounting for subsistence items which have become unfit for human consumption. No matter what the circumstances may be, the end result of a survey is to provide a method of expending unusable subsistence items from the books.

If subsistence items are missing, a survey is a means of finding out what happened to them. If subsistence items are unfit for human consumption, a survey is for the purpose of investigating how the damage or deterioration occurred, who was responsible, and what should be done with the subsistence items. In either case, the survey is basically a MEANS OF EXPENDITURE.

Types of Surveys.—Surveys may be formal or informal. A FORMAL survey (fig. 7-9) is made by

a commissioned officer appointed by the commanding officer, or by a survey board appointed by the commanding officer. The board consists of three officers, one of whom, and as many as practicable, must be commissioned. Formal surveys are required for certain classes of material or articles designated by the bureau or office concerned. In the absence of instructions by higher authority, the commanding officer determines the type of survey required. When it

Figure 7-10.—Expending subsistence items without survey.

79.11:43.3

8559

appears that responsibility for lost or damaged material may be placed on a person or persons in the naval service, a formal survey is required at all times.

An INFORMAL survey is held for routine matters where it appears that no disciplinary action is required. The distinguishing feature of the informal survey is that the commanding officer appoints the head of the department having custody over the material to be surveyed as the surveying officer. However, a special officer, not a member of the supply department, is appointed by the CO as permanent survey officer for subsistence items, usually the medical officer or junior medical officer.

The medical officer makes a careful inspection, then indicates whether the subsistence items should be destroyed. He recommends disposition of the surveyed subsistence items and indicates whether the items have any salvage value, and if salvage is practical and economical. When sale of items is a possibility, this recommendation is made.

Subsistence items may be expended without formal or informal survey procedure when culpable responsibility is not involved and when:

1. Material is short, damaged or lost in shipment and the value of the loss is less than $10 per receipt document.

2. Material is lost as a result of physical deterioration, damage in handling, fire, water, or other similar circumstances and the value of the loss is less than $100 per line item.

The above losses should be itemized on a subsistence Expenditure Log. The entries should be made in ink at the time of loss and signed by the accountable officer. Each expenditure also should be posted by the officer Storekeeper to the "OTHERS" column of the Subsistence Ledger (S. and A. Form 335) as occurring, and the balance on hand reduced accordingly. The following information should be recorded in the Expenditure Log for each loss.

1. Date
2. Stock number
3. Item name
4. Quantity and unit of issue
5. Unit price
6. Total value
7. Reason for expenditure
8. Signature of accountable officer

The above record may be maintained on a Survey Log (S. and A. Form 976). When the S. and A. Form 976 is used for this purpose, change the form as annotated in figure 7-10.

At the end of each accounting period and upon relief of the accountable officer, the Expenditure Log must be closed and the "Total Value" column totaled. One "Money Value Only" Invoice (DD Form 1149) is then prepared for the total value of all entries made in the Log during the accounting period. The following statement signed by the accountable officer should appear on the DD Form 1149: "To cover losses of subsistence items expended without survey during the period _____ _____," see figure 7-10.

The invoice number is posted opposite the total as the last entry in the Expenditure Log. A copy of the invoice is used by the office Storekeeper to post to the Record of Receipts and Expenditures (S. and A. Form 367), and is then retained by the accountable officer. The value of the invoice should be included in the survey caption in the "expenditure" section of the General Mess Operation Statement (S. and A. Form 45) and the invoice forwarded with the required returns.

The Expenditure Log and a copy of the DD Form 1149 should be retained by the accountable officer for a period of 1 year, after which they may be destroyed. During the 1-year retention period, these records should be made available to inspectors during the course of supply and general mess inspections.

ecce 8560

CHAPTER 8

SANITATION IN THE GENERAL MESS

Outbreaks of food-borne illness continue to be one of the problems encountered in mass feeding operations. Most outbreaks are preventable, since the most common causes are failure of food service personnel to practice good personal hygiene habits and sanitary techniques.

In addition to the hazards of accidental contamination with which mess personnel have always contended, modern warfare has added others. Nuclear, biological, and chemical agents may be used in any future war. Protection of the food supply and decontamination measures in the galley and mess would be vital to defense of the ship or station.

FOOD-BORNE ILLNESSES

There are two main types of food-borne illness. In one type, the food actually contains poison. This poison may be introduced into the food naturally, as in the case of poisonous mushrooms and certain tropical fish. It may be introduced accidentally, as in the case of food cooked in utensils that introduce harmful chemicals, or bacteria may grow in the food and produce toxin (poison) before it is eaten. This type is considered not an infection but an intoxication, or poisoning.

The second main type of food-borne illness is caused by food that serves merely as a carrier of bacteria or animal parasites. After the food is eaten these plant or animal parasites multiply in the person's body and cause an infection.

A third type of illness produced by food is that which may be caused by a wide variety of allergies, transmitted by specific foods eaten by individuals allergic to those foods. These illnesses are not caused by lack of sanitation, and there is little or nothing that food service personnel can do about them. If an individual becomes ill from eating a food that others eat without ill effects, he should consult the medical officer about the possibility of an allergy.

Bacteria

An understanding of bacteria is valuable to all personnel and essential for those who work with food in any way. Bacteria are one-celled plants so small they are visible only under a microscope. They are widely distributed in the air, water, soil, and animal and plant tissues. Bacteria are classified by shape. Those round in shape are called COCCI; the rod-shaped, BACILLI; and the spiral shaped, SPIRILLA.

The fact that bacteria cannot be seen makes careful adherence to sanitation principles necessary. Bacteria can move of their own accord only in liquids and cannot leave a fluid surface unless transported as "passengers" by other agents such as dust, food, dishes, silverware, cooking utensils, dirty fingers or fingernails, a common drinking cup, a hand towel, moving air or water, insects, or rodents.

Bacteria reproduce themselves by simply dividing in half. On the average, each germ, under favorable conditions, will divide and become two germs every 20 minutes. The multiplication or growth of bacteria is affected by heat and cold. Boiling temperature will kill all bacteria and freezing will retard their multiplication. Some bacteria will continue to grow at refrigeration temperatures, while others can withstand high temperatures. When refrigeration is used to prevent the growth of bacteria, the temperature must be cold enough to accomplish its purpose. Cold—even freezing—will not kill bacteria. When thawed they become active again.

Not all bacteria are harmful or disease producing. Some are simply undesirable, causing putrefaction. Others are beneficial; for example, the bacteria used in the culture of cheese and sauerkraut. Some are benign, neither harmful nor beneficial.

Bacterial Food Poisoning

Certain types of bacteria, if allowed to grow and multiply, produce TOXINS or poisons. If

these bacteria are present in food, the toxins cause illness.

Staphylococcus.—The most common of all food poisonings is caused by the staphylococcus germ. It is found in the throat, on the skin as a causative agent of pimples and boils, and in great abundance in the postnasal drip of people recovering from colds. Food-service personnel with colds, sore throats, infected cuts, or other wounds or sores may be responsible. The germs are transmitted to food by food-service workers who cough or sneeze into food, or by one who rubs pimples on his face and then handles food or the business end of utensils. Men with any of these ailments should not be allowed to handle food.

Staphylococcus bacteria must have a suitable medium or food in order to grow. Tenderized ham, cream filled pastries, salads, chopped foods, and cured meats are most often responsible for staphylococcus food poisoning. Foods can contain sufficient toxin to cause food poisoning and yet have no odor of spoilage and no abnormal taste. Once the toxin has been allowed to form in food, cooking will not make the food safe. Refrigeration prevents the bacteria from producing toxin but will not destroy it once it is formed. Even when food has been properly refrigerated, it can become contaminated by germs while being prepared or while standing in the galley before being served.

Botulism.—Botulism is a second type of food intoxication. This disease, usually fatal, is caused by the toxin produced by the rod-shaped bacterium called clostridium botulinum. Botulism germs are found in the soil and gain access to foods through contact with soil and dust and possibly water. The foods most often responsible are either canned or fermented. The preserving process has not been properly performed and has not succeeded in destroying the bacteria in the food. The botulinum grows and multiplies in an airtight container. Commercially canned foods are considered safe. However, when cans are damaged, leak, bulge, or are sprung, the contents are presumed to be unsafe.

The botulinum organism sometimes produces a gas and a cheesy odor in food, but the absence of these signs does not necessarily mean the bacteria are not present.

Bacterial Food Infections

Certain types of bacteria that cause gastrointestional diseases are transmitted through foods. The general symptoms are sudden onset of a gastrointestinal disturbance usually 6-72 hours after eating.

Food infections usually are transmitted by foods infected and allowed to remain at room temperature for a length of time. Foods most commonly involved are: custards, milk, cream, ice cream, sea foods, meats, eggs, meat products, shellfish, salads, mayonnaise, salad dressings, poultry dressings, bread puddings, cream pies, eclairs, and filled pastry.

The chain of infection is from a person who is presick, sick, and/or a carrier; by droplets falling directly into the food or hands touching it; and sometimes from utensils that have been contaminated.

Salmonellosis.—Salmonella bacteria must be present to produce infection. This illness usually is contracted from undercooked, semi-cooked, or raw foods, or from foods infected after cooking by persons who are harboring the germs and giving them off in intestinal discharge.

Since salmonella bacilli leave the body through the intestinal tract, the main source of salmonella infection is the person who does not wash his hands after leaving the head and who consequently contaminates all the food he handles.

Mice, rats, and cockroaches may contaminate food by the mechanical means of dragging filth over food and food utensils, or by intestinal deposits brushed off into food or containers.

While no specific food may be said to be responsible for salmonellosis, the most dangerous foods probably are: (1) those that are usually eaten raw, such as salads and greens; (2) cooked foods that are not reheated thoroughly, such as turkey dressings, fish, and poultry; (3) foods that are undercooked, especially poultry and uninspected meats; and (4) infected eggs that are eaten raw or undercooked.

Streptococcus.—Infections such as septic sore throat and scarlet fever are transmitted by contaminated milk and by certain other foods, including meat, meat products, and dressings. A type of this infection also causes gastrointestinal disturbance. Floor dust is one of the modes of transmission.

Typhoid Fever.—Typhoid fever is transmitted by milk, shellfish, or water supplies that have become polluted with the urine or feces of a person harboring the organism of this disease. It is also spread by carriers and by flies which transport the typhoid germ from soiled articles to foods, dishes, and cooking utensils.

Bacillus Dysentery.--Bacillus dysentery is transmitted by contaminated foods or water, by carriers, or by flies. The bacilli of this disease are found in the bowel discharges of infected persons.

Other Types of Cell Life

Other types of cell life which may or may not be harmful are molds and yeasts.

Molds.—Composed of many cells, molds may be very small or large enough to cover an entire wall. They grow best in dark, damp places, where temperatures are favorable. Some molds are valuable in the production of medicines such as penicillin; other molds may cause certain infections in human beings.

Molds spoil the taste of food and eventually destroy it. Mold may be removed and the remainder of the food used. If in doubt about using foods that have molded, consult the medical officer.

Yeast.—Like bacteria, yeasts are single-celled. They reproduce by budding. When a bud becomes sufficiently large, it is pinched from the original cell and becomes an independent cell. Certain yeasts are used in bread making, vinegar fermentation, and the manufacture of beverages.

Illnesses From Animal Parasites

Animal parasites sometimes enter the body in food and produce infections. Some of these forms of animal life are one-celled; all are so tiny they are not visible when the food is being prepared.

Amoebic Dysentery.—This illness is caused by a one-celled animal, the amoeba. These organisms eat the red blood corpuscles of the body and also the cells which line the intestines. The dysentery producing amoebae are transmitted by foods served cold and moist, such as celery, lettuce, and other fresh vegetables, or fresh berries. These foods may be infected by human carriers, by flies, or by having been grown in fields where excreta were used as fertilizer.

Trichinosis.—Eating infected pork that has not been cooked enough to kill the trichinella worm causes trichinosis. Since there is no sure way of knowing whether this parasite is present, pork must ALWAYS be thoroughly cooked.

Pork Tapeworm Infection.—Similar to trichinosis, the pork tapeworm is an infestation transmitted by eating infected pork that has not been cooked long enough to kill the cysts of the worm, and also by accidentally ingesting pork tapeworm eggs.

Beef Tapeworm Infection.—Beef tapeworms are transmitted by eating infected beef that has not been cooked enough to kill the encysted larvae. In order to prevent ingesting the beef tapeworm, use Government-inspected beef only. If it is necessary to use beef that has NOT been inspected, freeze it at 14°F or below for 5 days or longer, or pickle it in 20-25 percent salt solution for 5 days or longer. Cook it well done and never serve it rare.

Fish Tapeworm Infection.—Fish tapeworm comes from infested fish that is not thoroughly cooked. The symptoms consist of nervous disorders, digestive disturbances, abdominal pains, anemia, and symptoms of peptic ulcers. They appear after an incubation period of 8 to 12 weeks.

For safety, always see that fish is thoroughly cooked, and that it is never tasted raw.

Poisonous Plants and Animals

In your tours of duty as a Commissaryman in the Navy, you will learn of many new foods that are not common to the United States.

Every effort is made to keep poisonous plants and animals off the ship. But sometimes they do get aboard. Toadstools, hemlock, mussels such as those found on the west coast during the summer, tropical fish such as toadfish, puffin fish, certain members of the jack fish family, and, in tropical waters, barracuda at certain seasons of the year can cause poisoning and death. The symptoms are predominantly of a nervous nature including weakness or paralysis, numbness, tingling of the ears, and apprehension.

Some types of mushrooms contain natural poisons. Only an expert can decide whether or not a certain mushroom is fit to eat.

The safest rule is never use strange plants and animals for food unless your medical officer approves their use.

Chemical Food Poisonings

Some food-borne illnesses are caused by chemical poisons, but usually chemical poisoning is rare compared to bacterial food poisoning.

8563

ONLY THE COOKING UTENSILS OFFICIALLY FURNISHED BY THE NAVY SHOULD BE USED. IF IT IS EVER NECESSARY TO USE OTHERS, SEE THAT THEY ARE NOT OF THE TYPES DISCUSSED IN THE FOLLOWING PARAGRAPHS.

ANTIMONY POISONING has been caused by eating food cooked in poorly coated or chipped gray enameled cooking utensils.

CADMIUM POISONING may take place if chilled acid foods or drinks are allowed to stand in cadmium-plated metal containers before they are served. Illness may strike 10 to 15 minutes after the food is eaten. Lemonade, fruit punch, tomatoes, raspberry gelatin dessert, and tea which contains lemon juice can be contaminated by cadmium. Ice trays and metal pitchers plated with cadmium have caused chemical poisoning when filled with cold acid foods.

Both antimony and cadmium poisoning cause vomiting, cramps, and diarrhea about one-half hour after the contaminated food is eaten.

TIN POISONING is practically unknown. It is now thought that reported outbreaks of tin poisoning were due to other causes. It is not true that food spoils more quickly when standing in an open tin can than when removed from the tin can and stored in a dish. Spoilage comes from bacteria growing in the food, not from the tin can. In fact, contamination by bacteria is less likely to take place if the food is left in the sterile (free from bacteria) can than if it is placed in a dish that has not been properly washed. The precaution to remember is that leftover food must be refrigerated.

ZINC POISONING in food is rare. It may occur when acid foods are cooked in galvanized iron kettles. Outbreaks have occurred when apples have been cooked in this type of kettle.

LEAD and ARSENIC sometimes used to spray fresh vegetables may cause these foods to become poisonous. Be sure all fresh fruits and vegetables are thoroughly washed before you cook them. LEAD POISONING may also result from the ingestion of food or water which has been in contact with lead pipes, lead-plated equipment, and lead-soldered pots and pans. Lead is a cumulative poison, and small doses accumulating in the body will eventually cause chronic lead poisoning.

FLUORIDE POISONING is caused by sodium fluoride—a substance often used to get rid of waterbugs or cockroaches. It is a white powder that can easily be mistaken for baking powder. Keep all containers for such poisons out of the galley and bakeshop.

METHYL CHLORIDE POISONING is caused by leaking mechanical refrigerators. Check your equipment for such leaks.

METHODS OF PRESERVING FOOD

Although bacteria have been discussed as the cause of food-borne illnesses, they also cause food spoilage either by actually eating the foods and leaving their waste products in them, or by producing toxins inside the foods.

Foods are protected from bacteria spoilage by several methods employing heat—pasteurization, cooking, dehydrating, and smoking. They are also protected within limitations, by refrigeration.

Effects of Heat

There is a definite relation between the temperature and the length of time required to kill bacteria; the higher the temperature, the less time required. This is known as the thermal death rate of bacteria. Below a certain temperature (140°F), however, the bacteria are not killed no matter how long they are kept hot.

Pasteurization.—Destruction of all harmful bacteria in certain foods, notably milk and milk products, is accomplished without actually cooking the foods. There are two methods of pasteurization:

1. Holding method, in which milk is held at a temperature of 143°F for not less than 30 minutes.
2. Short-time high temperature (flash) method, in which the milk is held at 160°F for not less than 15 seconds.

Since acid, or sour-tasting foods, are generally capable of destroying bacteria at a lower temperature, such foods as fruit juices, pickles, and sauerkraut, frequently are pasteurized rather than subjected to high temperatures.

Cooking.—Cooking is the most important operation for destroying all harmful and most food spoiling bacteria. Cooking cannot, however, be considered a sterilization process because some heat-loving bacteria are not destroyed by it. These heat-resistant bacteria fortunately, do not affect canned food since conditions are unfavorable to their development.

Dehydrating.—Dry heat is sometimes used to dehydrate fruits and vegetables in order to preserve them. In this case, however, the heat does not destroy the bacteria but simply removes one of the conditions essential for their growth—MOISTURE. Should any dried food come in contact accidentally with water during storage, the food will quickly deteriorate due to bacterial activity.

8564

Many little unconscious habits are highly unsanitary. For example, putting the fingers in the mouth, scratching the head, or rubbing the ear. It is important to become aware of these habits and to control them as much as possible. In any case, remember always to wash your hands before touching food or utensils.

Another unsanitary practice is sticking fingers into food for tasting purposes. The proper way to taste food is to use two spoons—usually the soup spoon size. Use one to dip out a tasting sample; transfer it to the second spoon for tasting. Always use two spoons. Never use the spoon used initially to prepare the food. When one spoon is used, there is the temptation to use it to dip another taste sample.

Bathing daily and wearing clean work clothes and hat are other important personal hygiene habits.

PRECAUTIONS IN FOOD PREPARATION

Study of the previous pages should make it increasingly evident that the food service worker is the most important link in the transmission of disease through foods. His health, personal habits, and methods of preparing and serving food are of concern not only to himself but to his shipmates as well.

Most food-borne disease outbreaks are due to three things: (1) preparation of food too far in advance; (2) poor refrigeration; and (3) careless handling.

The following precautions should be observed in preparing and serving food:

1. Prompt service or refrigeration—Food should be served promptly after it is prepared. Otherwise, it should be refrigerated or kept hot. This is the general rule. How this rule applies to specific foods is explained in items 2 through 7.

2. Handling cooked foods—Protein foods which are not served immediately after cooking should be either chilled to temperatures of 40°F or lower (but not frozen) or held at 140°F or higher. Protein foods include meats, fish, poultry, gravies, meat stocks, soups, eggs, custards, cream fillings, and milk. Growth of harmful bacteria and the development of toxins (poisons) formed by the bacteria occur rapidly in cooked protein foods during holding at temperatures between 40°F and 140°F. Cooked protein foods that have been held at temperatures between 40°F and 140°F for more than 3 hours should be considered unsafe for consumption and must be destroyed.

This principle is known as the 3-HOUR RULE. If the product is refrigerated at intervals and then permitted to warm up, the total time of the various periods between 40°F and 140°F must not be more than 3 hours. Protein foods composed of ingredients which are hand-peeled, hand-sliced, or hand-diced after cooking should never be used as leftovers; the 3-hour limit between temperatures of 40°F and 140°F is usually taken in preparing, chilling, and serving the food. These foods include potato salad, chicken salad, macaroni salad, shrimp salad, egg salad, and similar items. Hand preparation not only increases the chance of contamination, but generally increases the length of time that these foods are held at room temperatures. It is also dangerous to return opened jars or bowls of mayonnaise and cooked salad dressing from salad bars to refrigerators for reuse at a later meal. Because of the danger of miscalculation of total elapsed time that these salad dressings have been held at temperatures between 40°F and 140°F, mayonnaise and cooked salad dressings should be placed on the salad bar in small quantities and must not be returned from the salad bar for reuse as leftovers.

3. Handling leftovers—When leftovers or warm foods are chilled, care should be taken to assure prompt and thorough chilling (40°F or below) to the center of the food mass. Foods that are to be refrigerated should be placed in shallow pans to a depth of not more than 3 inches and should be covered with lids or waxed paper. Such foods should not be put in large deep pans as chilling may take so long to get to the center of the food mass that sufficient time is allowed for the growth of harmful bacteria and the development of toxins. Guard against any procedure that might delay cooling. Food to be chilled should be placed in the chill box immediately. Leftover food should not be saved for more than 36 hours. Freezing leftovers is prohibited.

4. Handling ground food—Food that has been ground or chopped and is to be cooked later or incorporated in a made-dish should be refrigerated immediately. Such ground or chopped food should be refrigerated in shallow pans filled to a depth of not more than 3 inches and should be covered until cooked. When food is ground, an increase in the area of contamination and growth of harmful bacteria results. When chilled foods are ground, the grinding process warms the food to the point where bacterial growth may start.

5. Meats that are cut, sliced, or diced should be placed in shallow containers, covered with lids or with waxed paper, and refrigerated

8566

immediately. The temperature of the meat cutting room should be maintained at 50°F to 60°F. Improper handling of meats can result in souring as well as disease transmission.

6. Frozen foods should be thawed in the refrigerator. Freezing breaks down tissue and because of it foods can be invaded by germs more rapidly. Foods once frozen then thawed should not be refrozen. If not eaten, store under 40°F.

7. Keep milk and milk products under refrigeration at all times. This means keeping them chilled on the serving line.

8. All pork should be thoroughly cooked; raw and rare pork always should be avoided. Masses of food like spaghetti should be stirred thoroughly during cooking so that the cooking will be complete to the center of the mass.

9. Fresh fruits and vegetables should be washed thoroughly under running water to remove any particles of filth, or to remove poisonous insect sprays. Green vegetables of uncertain origin should be suspected as being contaminated with pathogenic organisms and chemically sanitized by immersion for at least 15 minutes in a 100 ppm (parts per million) available chlorine solution or 30 minutes in a 50 ppm available chlorine solution (or other approved methods) and thoroughly rinsed with potable water before being cooked or served. Head items such as lettuce, cabbage, celery, etc., must be broken apart before sanitizing.

10. Food in storage or left standing in the galley needs to be protected from contamination from flies, dust, coughs, and sneezes. Keep food covered.

11. Store food off the deck.

12. Preparation tables and work tables should be kept clean.

13. Kitchen utensils, meat grinders, and other similar equipment should be kept clean and handled properly. Food that comes in contact with equipment that is contaminated becomes contaminated.

14. Wash your hands before preparing food.

15. Don't cough, sneeze, or talk over food while it is being prepared or served. It can be contaminated with unseen droplets.

16. Don't smoke while preparing food. Saliva can be dropped on foods very easily when smoking.

17. Keep fingers away from mouth, lips, face, and soiled surfaces.

18. Foods should be handled as little as possible.

19. Use tongs to handle butter, doughnuts, bread, and other similar items of food. Do not use your hands.

KEEPING UTENSILS AND EQUIPMENT CLEAN

All phases of sanitation in a general mess are important. However, one of the most obvious is the proper cleaning and sanitation of equipment used for preparing, handling, cooking, and serving food and the proper cleaning and sanitizing of trays, dishes, and mess gear.

Dishes may be washed by hand or by machine. Whatever the method, the final results may be either excellent or poor, depending upon your knowledge, skill, and conscientiousness as a dishwasher combined with the equipment and materials provided for your use. Unless you operate a machine properly, it is worthless. The best equipment and detergents are not complete answers to good dishwashing.

Types of Soil

Unless galley and mess equipment and utensils are thoroughly cleansed, food particles in which bacteria may grow will remain on them. These food soils are divided into several distinct types:

1. Freshly deposited soil—the soil that remains immediately after use of the equipment or utensil.

2. Thin film—the soil that remains as the result of ineffective cleaning, or following a flushing with plain water. Thin films are easily seen, and they are capable of sustaining germs.

3. Built-up deposits—the result of ineffective cleaning methods which permit a day by day accumulation of soil.

4. Dried deposits—accumulations that result from drying action and frequent formation of a heavy crusty deposit.

5. Baked deposits—deposits that have been baked onto equipment and have become difficult to remove.

6. Burned deposits—materials burned into equipment surfaces by high heat. These are the most difficult to remove.

Removing Stubborn Soils

The Navy procures the correct type of detergent to be used in washing food preparation utensils and equipment. Hot water also provides temperatures that increase the chemical activities of the various ingredients in properly compounded detergents. Friction is an important part of cleaning. The required friction may be applied by brushing with approved brushes or by strong flushing, as in dishwashing machines. Hard abrasives should never be used on any metal

8567

surface. They result in scratches which provide lodging places for soil. It is recommended that pots and pans, cooking utensils, and other such items be presoaked to loosen any food clinging to the utensil. Then, using the proper detergent compound and hot water, wash the utensils, pots, and pans. A detergent increases the effectiveness of the water as a cleaning agent, and the washed pots and pans must be rinsed with hot water at 125°F then sanitized for one minute in hot water of 180°F. Once washed and sanitized, the clean pots and pans should be stored, bottoms up, in clean racks. Otherwise, the effort spent in washing and sanitizing is wasted.

See figure 8-2. This figure illustrates the temperatures necessary for the proper cleaning and sanitizing of food service equipment and utensils.

Hand Dishwashing

The equipment for manual dishwashing varies from one-compartment sink to the preferred three-compartment sink. A booster heater should be installed under the final rinse compartment, plus remote dial thermometers. Regardless of the type of sink on board your ship or station, follow the correct procedure for dishwashing as outlined below:

1. You should have the following: hot water, detergent, bacterial agent (chlorine or other), scraper, garbage can, and long-handled baskets.
2. Scrape gross food residue from all mess gear.
3. Sort and stack mess gear by type. Chipped or cracked glasses or dishes should be discarded at this point.
4. Preflush all mess gear with warm water to get rid of gravy, sauces, and other surface food residue.
5. Wash the mess gear in hot (110° to 125°F) water with the amount of detergent recommended for use when dishwashing by hand.
6. Place each item in basket; prerinse in hot (120° to 125°F) water. (Use separate baskets for dishes, cups, and glasses.)
7. Rinse and sanitize mess gear in hot (1[illegible]°F) water for 1 minute or at least 2 minutes at 170°F or in chlorine solution containing not less than 50 parts per million residual chlorine for 2 minutes.
8. Lift the basket out of the hot water; place it on the drainboard and air dry.

Figure 8-2.—Temperatures necessary for the proper sanitizing of food service equipment and utensils.

After the dishes have been washed and sanitized, the residual heat left in them aids in rapid air-drying. DO NOT DRY MESS GEAR (OR KITCHEN EQUIPMENT) WITH A TOWEL, since many bacteria may be added to a utensil by an unclean dish towel.

Soaps are prohibited in hand or machine dishwashing.

Machine Dishwashing

Dishwashing machine used in the Navy are classified as one-tank, two-tank, or three-tank machines. The three-tank machine is a fully automatic, continuous racking machine which scrapes, brushes, and provides two rinses. It is used at major recruit installations and other large activities.

Single-tank Model.—Single-tank machines (fig. 8-3) are used only on small ships where, because of space and weight considerations, larger models are not feasible.

In order to control the bacteria to a satisfactory minimum in single-tank machines, it is necessary

48.34

Figure 8-3.—Typical semiautomatic single-tank dishwashing machine.

0728569

that the temperature of the wash water in the tank be 140° to 160°F. Consequently, a thermostat is provided in the automatic machines to prevent operation when the temperature of the wash water is below 140°F. This higher operating temperature results in less efficient removal of food particles when certain starchy and albuminous foods are served. Therefore, the washing time is extended in the automatic machines to 40 seconds. For best results, soiled dishes should be prewashed by hand in warm water containing detergent before placing them in single-tank washers.

Rinsing is accomplished by means of hot water which is sprayed on the dishes from an outside source, and is controlled by an adjustable automatic steam-mixing valve which maintains the temperature of the rinse water between 180°F and 195°F.

In order to conserve fresh water, which must come from the ship's hot water system, the rinse time interval is limited to 10 seconds. When the water supply is not a problem, a rinse of 20 seconds is recommended.

Wash and rinse sprays are separately controlled by automatic, self-opening and closing valves in the automatic machine, or by handles in the manually operated machine. The automatic machine provides for a 40-second wash and a 10-second rinse; for manually operated machines, wash and rinse intervals are controlled by the operator who should allow this same time for washing and rinsing.

Double-tank Method.—Double-tank machines (fig. 8-4) are available with several different capacities and are used when more than 150 persons are to be served. These machines are provided with separate wash and rinse tanks and also have a final rinse of hot water sprayed on the dishes from an outside source and controlled by a self-closing valve opened by the racks which pass through the machine. The final rinse is controlled by an adjustable automatic steam mixing valve which maintains the temperature between 180°F and 195°F. Double-tank machines are also equipped with a thermostatically operated switch in the rinse tank which prevents operation

Figure 8-4.—Typical automatic double-tank dishwashing machine.

48.35

Loc8 8570

of the machine if the temperature of the rinse water falls below 180°F. The racks pass through the machine automatically by means of conveyor chains. The two-tank dishwashing machine should be timed so that the utensils are exposed to the machine sprays for not less than 40 seconds (20-second wash, 20-second rinse).

Operating Dishwasher

The first thing you should do is to read and become familiar with the operating instructions included on the instruction plate which is mounted on the hood of the machine you are operating. Always follow these instructions, or you may damage the equipment or injure yourself and others.

The following detailed instructions are given for double-tank machines since most machines in service are of this type. These directions are also generally applicable to single-tank units, except for wash and rinse time intervals and temperatures.

1. Inspect the machine to see that the wash tank is clean and all spray openings are free from food particles, strings, and other obstructions.
2. Close the drain valves on both tanks.
3. Open the water valves and fill both tanks to the level marked on each or up to the overflow line. When tanks are filled, close the water valves tight.
4. Open the steam valve and heat the rinse tank water to 180°F or higher (not to reach vaporization point). Leave the steam valve on the rinse tank open so that the temperature does not fall below 180°F during operation of the machine. Machines are provided with a valve so that the final rinse temperature is 180°F or above. This adjustment must be made with the final rinse valve open.
5. On conveyor type machines, set the conveyor speed so that the dishes receive a minimum wash of 20 seconds and a minimum rinse of 20 seconds.
6. Add detergent. See Operation and Maintenance of Dishwashing Machines (NavShips 250-522) for the amount of detergent required for the wash tank size and the type of water being used.
7. Push the start button to start the pumps and conveyor. The rinse tank is fitted with a thermostat which, if properly set, will prevent the motor from starting until the temperature of the rinse tank has reached 180°F or higher.
8. Operate the machine for 1 or 2 minutes during which time the heat from the rinse spray should cause the temperature in the wash tank to increase gradually to 140°F.

At this point you are ready to start the washing procedure. However, it is important that dishes be thoroughly scraped free of solid food residues before being washed. Pre-cleaning will extend the useful life of the detergent in the machine, will prevent clogging of the pump and spray jets, and generally will result in improved cleaning performance. The dishes should be held over a conveniently located garbage can and scraped with an approved all plastic brush. Prewash all mess gear in the scullery sink prior to processing the dishwashing machine. Place scraped dishes in dish racks; cups, glasses, and containers should be placed upside down in appropriate racks so they are not filled with wash solution which cannot be washed away. Mess gear should never be nested since this prevents efficient washing and rinsing. Do not stack cutlery more than 1 inch deep in the rack.

9. Push the loaded dish racks into the machine on the conveyor until it comes up against the conveyor lug. With manually operated "push through" machines, be careful not to push the racks along too quickly since this practice will result in unsatisfactory cleansing. A minimum of 20 seconds should be allowed for each rack.
10. Maintain the temperature of the wash solution at 140° - 160°F. Higher temperatures will result in baking of egg and other protein solids onto the dishes.
11. Add $^1/_4$ of the original amount of detergent every ten minutes to compensate for the dilution and the increasing food particle load in the wash water.
12. Observe that as the first rack is discharged from the machine, the thermometer on the final rinse shows a temperature between 180° and 195°F.
13. Eating utensils should remain in the rack for approximately 1 minute for drying. When silverware racks are discharged from the machine, shake the rack slightly to get rid of entrapped water in the bowls of spoons and from the surfaces of all utensils.

Store dishes in a clean closed area to avoid recontamination, after being properly washed and cleaned.

The washing of silverware is often unsatisfactory because too much is placed in the rack for effective washing. A method of washing that avoids this difficulty is to sort the silver and place it in cylinder shapped compartments and run through the dishwashing machine. When the wash-rinse cycle is complete, the sanitized silver is inverted in like cylinder shaped

1658 8571

compartments, thereby accomplishing the washing and sanitizing without hands touching the utensils.

Cleaning and Maintenance of Dishwashing Machines

Clean and rinse the interior of the machine, spray arms, and strainer pans after each period of use (see fig. 8-5).

Brushes are provided for cleaning the removable spray arms which, after cleaning, should be replaced in the machine so that the spray is directed vertically and not against the sides of the machine. Check the machine for leaky valves and report leaks to the commissary officer immediately. Have all moving parts lubricated at regular intervals.

48.36

Figure 8-5.—Cleaning sprays, drains, and strainers of dishwashing machines.

1708 16 8572

Descaling Dishwashers

The accumulation of scale deposits in dishwashing machines is of public health significance for at least two reasons. FIRST—excessive scale deposit on the inside of piping and pumps clogs them and interferes with the efficient performance of the machine by reducing the volume of water that comes in contact with the utensil in the washing and sanitizing process. SECOND—scale deposits may provide a haven for dangerous bacteria.

The supplies needed for descaling are available through Navy supply channels. See the supply list below:

Stock Number	Description of Material
9G6810-264-6722	Orthophosphoric acid 85%, technical, 7-lb bottle
9G7930-282-9702	Detergent, general purpose, 1 qt bottle
9G7930-282-9699	Detergent, general purpose, 1 gal can
9G7930-282-9701	Detergent, general purpose, 5 gal drum

It is necessary to know the capacity of the dishwashing machine tanks. This may be determined by measuring (in inches) the inside dimensions of each tank, applying the following formula: length x width x depth (to water line) ÷ 231 = capacity in gallons.

Steps and key points are as follows:

1. Fill the tanks halfway to overflow level with hot clean water.

   If tanks are not fitted with water level indicators, remove a section of the scrap tray in each tank so that the overflow pipe can be seen.

2. Add the required amounts of acid and wetting agent to prepare the cleaning solution.

   Measure amounts carefully. Use 7 fluid ounces of orthophosphoric acid 85 percent plus $^1/_2$ fluid ounce detergent, general purpose, for each gallon capacity of the tank when filled to overflow level.

3. Complete filling tanks.

   Fill to the overflow level.

4. Put scrap trays, spray, and curtains in place.

   Scale deposits on all attachments must be removed.

5. Turn on machine.

   Operate the machine at the highest possible temperature for 30 minutes.

6. Turn off the machine and drain.

   Open the drain valves and allow all the cleaning solution to drain from the tanks.

7. Refill.

   Use fresh hot water.

8. Turn on the machine.

   Operate the machine at the highest temperature for 5 minutes.

Repeat steps 7 and 8 several times. The entire method should be repeated at such intervals as may be required to assure freedom from interference with efficient operation of the dishwashing machine.

RADIOLOGICAL WARFARE DEFENSE

Radiological defense includes all such measures as are taken to minimize personnel and material damage from radioactivity. The basic responsibility for this function resides with the damage control organization of the ship. Your basic guidance in radiological defense matters will be derived therefrom. Supply department personnel are normally assigned appropriate duties in accordance with the damage control plan. You should be aware of the plans and procedures to be followed on board your ship or station. Familiarize yourself with the appropriate portions of the following publications:

Disaster Control (Ashore and Afloat)
NavPers 10899-A
Basic Military Requirements
NavPers 10054-A

Emergency operations are those that immediately follow the blast. During this period, a realistic evaluation of the disaster is made, and initial steps toward recovery are taken. Protective clothing, monitoring equipment, and decontamination gear will be needed.

Radiological Contamination

Blast damage and thermal radiation may result in partial or in complete destruction of messing facilities and of subsistence items. The physical destruction of these facilities is important to the extent that food preparation and messing facilities are disrupted. Radioactivity is important for its effect on the human body.

8573

Because of its ability to penetrate matter deeply, gamma radiation is usually considered the most hazardous from the standpoint of external radiation. Since the principal source of alpha particles would be the unfissioned nuclear material of the weapon, the probability of significant alpha contamination from nuclear detonation is small. Beta particles likewise have poor penetrating ability (ordinary clothing will stop beta particles), entering the skin to a depth of about $^1/_5$ inch, but their ionizing power is about 100 times that of gamma rays. Ingested with food, inhaled, or entering through cuts within the body, beta particles meet no barriers and become particularly destructive when retained in the body for some time. Therefore, in food preparation and service, all forms of radioactivity should be regarded as hazardous.

Radioactivity may be induced in exposed materials close to the burst. Such items as soap, table salt, copper, or brass may become radioactive as a result of induced radiation (the action of neutrons). Radioactivity also may be carried by blast residues, the principal one being dust particles. A person contaminated by radioactive materials can easily contaminate an otherwise safe object or area. If he handles foods, the foods likewise can become contaminated. Radioactivity cannot be destroyed by cooking or sterilization, or neutralized by chemical treatment. It must be removed as completely as possible to a limit of radioactivity set by command authority in the light of existing circumstances.

Radioactive materials can only be removed by physical means. The extent of radioactivity existing in any commissary or messing space should be determined by survey with radiac monitoring equipment. This includes the galley, utensils, food for preparation, mess gear, the scullery, and all personnel involved in food preparation and service. If the survey so indicates, it may be necessary to reestablish the general mess in another area designated by the commanding officer as safe.

The supply officer is responsible for taking necessary precautions to ensure that the food served is free from radioactive contamination. Galleys and other food preparation spaces, food equipment, utensils, mess gear, and personnel engaged in the food service operation should be carefully monitored by qualified persons with appropriate monitoring equipment to ascertain the presence and the extent of radioactive contamination.

Decontamination operations should be carried out as required. Subsistence items in glass or metal containers or sealed in barrier-wrap packages will be the least likely to be contaminated. These should, nevertheless, be monitored, and care should be exercised upon opening such packages to avoid contamination. The fresh water supply should be monitored. Subsistence items should be monitored in their dry state because dilution with water will substantially lower the beta readings and the presence of alpha particles may not even show up on radiac instruments. All subsistence items, when they have been monitored, must be clearly marked as "contaminated" or "safe for use." All subsistence items should be cleared for use after monitoring if found to be within acceptable limits established by the local command in accordance with Radiation Health Protection Manual (NavMed P-5055).

Radiological Decontamination

There are various methods of removing contamination. They differ in effectiveness in removing the contaminant, in applicability to given surfaces, and in rate of operation. These, in general, fall into two classes, gross or rough decontamination and detailed decontamination. Gross decontamination consists of a rapid washing down with large quantities of water from a firehose or nozzle system. This class is generally not suitable for use in galley and messing spaces except for decks. Detailed decontamination procedures are characterized by more thoroughness. These procedures are costly in time, manpower, and material, but they are more effective. Detailed decontamination will be necessary in galley and messing spaces. Efforts to decontaminate with heavily contaminated water will obviously be ineffective; however, water contaminated to a less degree than the surface contamination to be removed may still be used to good effect. Water used for decontamination must be allowed to drain freely from contaminated areas. Water from tightly covered storage tanks should be safe and potable, provided the circulating system is tight. Water from open reservoirs cannot be relied upon as being free from contamination. Sea water in the neighborhood of an aerial burst to windward will be contaminated at the surface. A subsurface burst will heavily contaminate sea water in the vicinity. General knowledge of the local situation and a monitor survey should provide data on which a decision regarding the water supply will be based.

8574

When materials (cleaning agents) specifically designed for the removal of radioactive contaminants are available, they should be used in accordance with instructions. When they are not available, the following are suggested for general cleaning of galley surfaces:

Formula 1

Detergent, general purpose, liquid, water soluble, Type I...1/2 pound. Military specification MIL-D-16791

Sodium phosphate, tribasic, technical (trisodium phosphate)...1/2 pound. Federal specification O-S-642, Type II

Water, hot...(12 gallons)...100 pounds

Directions: The sodium phosphate should be completely dissolved by stirring into hot water. The sirupy liquid detergent should be added and stirred until thoroughly dispersed.

Formula 2

Dishwashing compound, machine, granular, free flowing. Federal specification P-D-425a (specify whether hard or soft water will be used).

Directions: The compound should be dissolved in hot water to make a 0.5 percent (approximate) solution (1 pound per 25 gallons of water). The solution should be used hot.

Formula 3

Citric acid, monohydrate, granular form. Military specification MIL-A-11029 (Cml) Change No. 3223

Directions: Citric acid should be dissolved by stirring to make a 3 percent (approximate) solution (3 pounds in 12 gallons of water). In use, utensils should be immersed and metal surfaces should be sprayed.

Except for citric acid, the above materials are commonly used and are readily available. The suggested formulas are not intended to take the place of agents specified in existing decontamination instructions. They constitute the bare minimum as substitutes and should serve to meet immediate emergency requirements. All chemical cleaning agents function most efficiently when hot. The choice of method and cleaning agent to be used should depend upon the nature of the surface to be decontaminated, the kind and degree of contamination, and the time, manpower, and materials to do the work.

Monitoring and Decontaminating Foods

All foodstuffs should be carefully monitored. Foods in metal or glass packages may be safe. Contamination is best removed from the external surfaces by washing. Food items in sealed dustproof packages may also be safe, provided the wrapper is not broken. To remove the contamination from these packages, vacuum them and carefully remove the outer wrap. Some vegetables can also be decontaminated if carefully washed, dried, monitored, and peeled, if monitoring shows contamination is not above specified limits. When surface contamination cannot be physically removed, the food should be condemned. All foods must be inspected and approved by the medical officer.

Decontaminating Spaces and Equipment

Thorough cleaning of all surfaces is a must. Work should be commenced overhead and continued downward in the direction of liquid flow. When feasible, the first step should consist of flushing the surfaces with clean water. DO NOT get water on electrical controls that are not waterproofed. The second step involves systematic scrubbing with chemical cleaning agents. Piping, duct work, stanchions, bulkheads, coamings, and decks should be repeatedly scrubbed until monitoring indicates that a safe condition exists. Bare metal surfaces should be given an initial scrubbing with alkaline detergents to remove grease film. When available, citric acid solution should then be applied and allowed to remain for a minimum period of 10 minutes. Rinse the surface with clean fresh water, allow to dry, and monitor. In the absence of citric acid, vinegar may be used, but is less effective.

Decontaminating Utensils and Mess Gear

Treat metal utensils and mess gear such as mess trays, metal tableware, and cutlery in the same manner as other metal surfaces. Wash with a detergent followed by an acid treatment. When possible, immerse utensils and mess gear in the acid solution. Crockery and glass present no particular cleaning problem, provided the glazed surfaces are without scratches and foreign deposits such as stains or hard water scale. Plasticware may present some difficulty because of the relatively porous character of the surface, scratches, and the presence of foreign deposits. Both glass and plasticware should be machine-washed, rinsed, dried, and each item monitored. Those that do not pass should be inspected for cracks and surface defects. Cracked and badly scratched items should be disposed of immediately. The other items still showing contamination should be

given repeated washings until safe, or they should be segregated to await natural decay of contamination or disposal of the item.

Protection of Personnel

When engaged in decontamination, wear protective clothing as prescribed by the ship's Damage Control Bill. If protective clothing is not available, similar garments may be substituted. Care must be taken that substitute clothing adequately prevents radioactive particles from coming in contact with the skin or gaining entry to the body by ingestion, inhalation, or through breaks in the skin. Masks should be worn. In the absence of regulation masks, goggles or glasses to protect the eyes and a filter improvised from several layers of turkish toweling worn over the nose and mouth to protect the lungs may be used.

Entrance into uncontaminated general mess spaces of any contaminated personnel and material should be prohibited. All personnel and material should be monitored and cleared before entering spaces requiring decontamination. Cleaning gear, items of protective clothing, et cetera, used in decontamination procedures should be segregated and disposed of as contaminated, according to their level of contamination.

To familiarize yourself with protective clothing and equipment, and with adapting regular issue clothing for NBC warfare protection, see Basic Military Requirements, NavPers 10054-A.

Avoidance of Recontamination

Contaminated items brought accidentally into general mess spaces should be removed and, pending decontamination of the affected areas, these areas should be roped off. Personnel who may have walked through these areas or who may have otherwise come in contact with radioactive particles should be sent to the decontamination station.

BIOLOGICAL WARFARE DEFENSE

Biological warfare is defined as the use of living agents, or their toxic products, to produce disease or cause the death of personnel, animals, or plants.

The chief objective of biological warfare is mass infection resulting in the incapacitation or death of large numbers of individuals or in the destruction of their sources of food, both animal and plant, or perhaps in both. The weapons of biological warfare, unlike most other weapons, act on living matter only and are limited in use to these objectives.

In case of a biological warfare attack, there are certain instructions that should be carried out for the protection and decontamination of eating, drinking, and galley utensils; galley and mess equipment; and messing spaces in an area contaminated by biological warfare agents.

Good sanitary and hygienic practices are the best defenses against many aspects of biological warfare. A close examination of the cleanliness of the general mess and strict adherence to the applicable instructions will improve biological warfare defense greatly.

The problems of biological warfare differ from ordinary military hygiene problems only in that hardier types of organisms may be present in other than their normal environment and in higher levels of contamination.

Biological Contamination

In treating the problem of biological warfare attack, it is assumed that there could be contamination of personnel, of all exposed surfaces, and of circulating air. Because of the current difficulty in rapidly detecting biological warfare agents, knowledge of contamination might (although not necessarily) be based on the occurrence of widespread or unusual sickness. This sickness could be caused by contamination that had occurred several days or weeks before. A situation could exist also whereby extensive employment of biological warfare would require additional precautions in the operation of all general messes. These instructions are intended for use in the event of suspected or known biological warfare attack. The problem is to decontaminate and prevent recontamination.

Decontamination Methods and Materials

Formalin vaporized by an insecticide fog applicator is an effective decontaminant and should be used under most circumstances for decontamination of galley and messing spaces. It is somewhat corrosive and leaves a disagreeable formaldehyde odor which is difficult to remove. Formalin vapor limitations are:

1. It is toxic to man.
2. It must remain 16 to 24 hours to be effective.
3. It damages delicate instruments.
4. Spaces must be aired for 24 hours after its use.
5. Masks, protective clothing, and rubber gloves must be worn.

8576.58

Ethylene oxide gas also is an effective decontaminant. It leaves no objectionable odors and is noncorrosive. It is, however, practicable only for small spaces, requires considerable preparation, and is not always available. It is used primarily to decontaminate equipment. Ethylene oxide gas limitations are:

1. It is highly explosive.
2. It is toxic.
3. Masks, protective clothing, and gloves must be worn.

If neither formalin nor ethylene oxide is available or if their use as fumigants is not feasible, the interior surfaces of the contaminated spaces should be scrubbed down with an effective detergent solution (discussed in the Radiological Decontamination section earlier in this chapter) to remove dust, grease, et cetera; next, hosed with clean, fresh, safe water to remove residual soil and detergent solution; then sprayed or scrubbed with water to which has been added 200 ppm (parts per million) available chlorine. Iodophors solution, phenolic solutions, or formalin solutions, although they are less desirable than chlorine, may be used if prepared as advised by the medical department.

Large equipment (those items too large to be immersed in sinks or run through dishwashing machines) should be washed, rinsed, and decontaminated in the same manner as prescribed for interior surfaces of messing spaces. Small items of equipment which will not suffer damage by immersion should be washed, rinsed, and sanitized in the dishwashing machine or by hand dishwashing as described earlier in this chapter.

Before eating and drinking utensils are brought to the scullery for decontamination, the interior bulkheads, all working surfaces (tables, dishcarts, and sinks), the interior and exterior of the dishwashing machine, and all other equipment used in the washing and sanitizing of eating and drinking utensils should be thoroughly washed, rinsed, and decontaminated as appropriate with formalin, ethylene oxide, or a detergent solution. Remember, both formalin and ethylene oxide are toxic to man, and therefore their use must be followed with thorough rinsing in safe water.

Eating and drinking utensils should be decontaminated by machine or hand dishwashing. A person who has handled contaminated utensils should not handle decontaminated utensils until he has been decontaminated. Decontaminated articles should not be placed in contact with any surface which has been exposed to contamination. If possible, use baskets or containers designed to hold silverware in a vertical position, handle down, during the washing and sanitizing processes, and additional containers of similar construction into which the silverware may be inverted without being handled by workers. If such containers are not available, lay the silverware flat in the racks with the handles extending in the same direction. Do not exceed a depth of two utensils. Take care when removing utensils from the racks after decontamination to prevent recontamination.

Sterilization by hypochlorite solution should be used only when dishwashing machines do not operate correctly. The utensils should be soaked, while still in the washrack, for one full minute at 100° - 140°F in a solution of one part hypochlorite and 50 parts water in a single-tank machine, or one part hypochlorite and 500 parts water in a double-tank machine; one-fifth of 1 percent of a detergent must be added to either solution. This solution may be mixed from nonionic detergent, FSN 9G6850-282-9699 through 9702, or solid nacconal detergent with any one of several chlorine containing compounds such as calcium hypochlorite, sodium hypochlorite (javelle water), or chlorinated lime.

In storage, compounds containing chlorine have been known to deteriorate. In this respect it will be necessary to have a qualified person from the ship's company to analyze the soaking solution for chlorine content to ensure that the proper concentration of available chlorine is attained and continued at sufficient strength.

After the sterilization soak and water rinse, cover the washracks containing the utensils with a cloth that has been sterilized by boiling. Do not transfer utensils to another rack. Ensure that personnel in the mess line pickup utensils from the washracks by touching only the handles.

Large equipment may be decontaminated by the use of hypochlorites. Hypochlorites are corrosive to all metals that will rust and should not be allowed to come in contact with motors and other electrical equipment from which such hypochlorites could not be thoroughly wiped off. After decontamination, cover as much of the equipment as possible with sterile cloths.

Avoidance of Recontamination

Recontamination may be caused by secondary aerosols which resettle organisms on surfaces or contaminate the air that is breathed. Secondary aerosols are clouds formed from particles (bacteria or other organisms) which, having been deposited on a surface, are stirred up into the air again by scuffing, shaking, or other mechanical

128577

action. Secondary aerosols may be suppressed by wetting surfaces with oil or water.

It is important to ensure that, before entering the mess spaces, Commissarymen and all personnel eating in the mess spaces are as free as possible from contamination. The medical officer should be consulted on the decontamination of food service personnel. In cold weather, personnel in the mess lines should be required to remove outer garments and leave them outside the mess spaces prior to entering the messing area. It has been found that removing clothing will shake off organisms which have come in contact with the surfaces, thereby setting up secondary aerosols. Do not permit unauthorized personnel in mess spaces.

Decontaminating Subsistence Items

The advice of the medical officer must be sought before any attempt is made to decontaminate food suspected of biological warfare contamination.

Dry Subsistence.—Food packed in containers that are resistant to the passage of biological agents (sealed containers made of metal, plastic, glass, or porcelain) requires only that proper exterior decontamination be performed. Paper labels and paper covers must be removed from the container and one of the following methods of decontamination should be used:

1. Immerse the containers for 15 minutes in a solution of water to which 200 ppm (parts per million) available chlorine has been added; the containers are then rinsed with potable water.
2. Soak the containers for a minimum of 15 minutes in effective detergent solution as an expedient method to reduce contamination to a safe level (see formula 1 discussed under the heading "Radiological Decontamination"); the containers are then rinsed with potable water.
3. The exterior surfaces of stacks of food packed in impermeable packages can be sterilized by vapor disinfectant, such as formalin or ethylene oxide.

Food packages which will not stand immersion must be wiped off with a solution of water to which 200 ppm (parts per million) available chlorine has been added and the food thoroughly cooked before eating.

Food packaged in sacks or other permeable containers can be decontaminated with ethylene oxide, but because of the limited availability of this product it is recommended that such foods be thoroughly cooked before eating.

Fresh or Chill Items.—Foods that can be peeled or pared may be decontaminated by soaking for 15 minutes in water to which 200 ppm available chlorine has been added. The food is then peeled or pared and rinsed well with potable water. This method has been applied satisfactorily to apples, potatoes, and eggs.

For other fresh or chill items the use of heat is the most practicable means of decontaminating contaminated foods. Thorough cooking will reduce contamination to a safe level so that food can be consumed. Specific methods to be followed in this form of decontamination are discussed later under the heading "Food Preparation Guidelines."

Frozen Items.—Food items stowed in freeze space in impermeable containers (canned frozen strawberries, for example) may be decontaminated by immersing the containers for 15 minutes in a solution of water to which 200 ppm available chlorine has been added; the containers are then rinsed with potable water.

Food items stowed in freeze space in permeable containers (frozen vegetables) may be decontaminated as outlined earlier for food packaged in sacks or other permeable containers.

Food items stowed in freeze space but not contained in outer packaging (meat, for example) must be completely thawed and thoroughly cooked before eating.

Additional Precautions.—Hands should be free of contamination during the opening operations to ensure that the contents are not contaminated. Opened cans of fruit, jam, jelly, or similar foods must be destroyed. Opened cans of vegetables may be decontaminated by boiling the vegetables for a minimum of 15 minutes in a steam jacketed kettle.

Food Preparation Guidelines

The use of heat is the most practicable means of decontaminating contaminated foods. In no case should decontaminated food be consumed until it is pronounced safe by a designated medical officer. It is recommended that, insofar as possible, only foods contained in impermeable packages (cans, bottles, jars) be decontaminated and used for meal preparation.

Food items which are not packaged or those that are packaged in permeable containers may be cooked by either of the following methods:

1. In a pressure type cooker at 15 pounds pressure at 250°F (121°C) for 15 minutes.
2. Boiling for a minimum of 15 minutes.

8578

Certain contaminated items may be decontaminated by baking. Only those recipes listed in the Navy-Marine Corps Recipe Service which specify an oven temperature of 400°F and above, for a cooking period of 30 minutes or longer, should be used to prepare baked items using contaminated ingredients.

All meats except those contained in decontaminated impermeable containers (canned meat items) must be cooked to the well done stage. Guidance cards in the Navy-Marine Corps Recipe Service include information on internal temperature indicating the well done stage.

Decontamination of Water

The detection of water contamination and the laboratory analyses are responsibilities of the medical department. Biological warfare decontamination of water is not difficult when regular water treatment facilities exist. However, more chlorine probably will need to be added during the ordinary processing of the water. If no water treatment facilities are available, water can be decontaminated by any of the following methods:

1. Boiling for 20 minutes.
2. By distillation, if equipment is available.
3. By using iodine tablets coupled with boiling.

A medical officer should pass on the method and the completeness of the decontamination process before water is used for drinking purposes. Water that has been decontaminated must be protected against further contamination.

CHEMICAL WARFARE DEFENSE

In chemical warfare, death, injury, or irritating effects are produced by toxic chemical agents. Although commonly called gases, actually these agents may be found also as solid particles or liquids. The term "chemical warfare agent" is a general expression applied to any chemical which, by its own action, can produce powerful casualty, harassing, screening, or incendiary effects.

Chemical Agents

Chemical warfare agents, like the biological warfare agents, are used chiefly for their effects on personnel, although some agents will have a corrosive effect on specific materials, and incendiaries will burn most materials. These agents produce a harmful physiological reaction when applied to the body externally, when breathed, or when taken internally. Most CW agents cause disorganization of the functioning of the body.

Descriptions of potential chemical warfare agents; methods of detection and identification of the various agents; material, equipment, and clothing to be used by decontamination personnel; and the methods of decontamination to be employed in the recovery of various areas, spaces, materials, and objects are published in Chapter 12 of NWIP-50-1.

The following paragraphs prescribe the methods of decontaminating eating, drinking, and galley utensils; galley and mess equipment; and messing spaces in an area contaminated by chemical warfare agents.

Decontamination

The contamination of general mess spaces and equipment depends on the chemical warfare agent used and the factors involved, such as method of delivery, the weather, and the various degrees of contamination (vapor, light liquid, and heavy liquid).

Vapor Contamination.—After the surrounding areas have been decontaminated, the general mess spaces should be aerated thoroughly and the entire messing space washed down inside and out with clean water. All equipment and utensils used in the preparation and service of food should be washed carefully using normal procedures. Spaces, utensils, and equipment then should be tested with the chemical agent detector kit and, if necessary, any of the prescribed procedures should be repeated.

Light Liquid Contamination.—The messing spaces, inside and out, should be washed with hot water. You may add an alkaline detergent, such as a standard dishwashing compound, and if applied at high pressure, it will increase the water's effectiveness. As an alternative method for mustards, you may apply a bleach slurry to all surfaces. After washing down, aerate the messing spaces. If slight contamination remains, the messing spaces should be heated to as high a temperature as possible for about 1 to 2 hours. Then the spaces should be opened and ventilated for 15 minutes. Repeat the procedure as necessary, testing at intervals with a chemical agent detector kit. Porous objects, such as meat blocks and wooden benches, will absorb liquid contamination to the extent that it probably will be necessary to destroy them. Metal, glass, or china utensils or any equipment which is not damaged by water should be immersed for 30 minutes in actively boiling water. Add 1 cupful of alkaline detergent to each 5 gallons of water.

8579

Upon completion of the boiling process, normal dishwashing procedures should be followed. Plastics generally cannot withstand boiling water and should be destroyed.

Heavy Liquid Contamination.—Heavy liquid contamination is unlikely, except from a direct hit, in which case recovery of the space and contents will be a major undertaking. However, when such is the case, the following procedures are recommended.

Spaces should be roped off or abandoned as unsalvageable, as no amount of washing or scrubbing of a porous surface which is heavily contaminated by a liquid chemical warfare agent (particularly mustard) is likely to do much good.

Metal, glass, or china utensils or any equipment which is not damaged by water, should be decontaminated in the same manner as prescribed in light liquid contamination discussed earlier.

Large equipment unsuited for immersion in boiling water should be scrubbed vigorously with DS2 solution or hot water and an alkaline detergent, rinsed, disassembled, and scrubbed again with particular attention to parts not reached by the first washing. The equipment then should be rinsed, dried, oiled, greased, and reassembled. Wooden items should be removed and destroyed.

On electrical equipment, unless the electrical unit is enclosed in a watertight seal, water must not be used in the decontamination process. Electrical equipment should be cleaned with trichloroethane, technical (methyl) chloroform, or DS2 solution. All greases must be removed, bearings cleaned, and the equipment regreased.

DS2 is flammable and irritating to the skin. Protective clothing and masks should be worn when it is used.

Careful inspection must be made of the general situation before large quantities of food or water suspected of chemical agent contamination are destroyed. Contaminated food and water must be destroyed in some cases; in other cases, they may be salvaged by special decontamination procedures. In any event, the responsibility belongs to the medical department to determine whether food or water contaminated by chemical agents should be decontaminated or destroyed. Decontamination should be accomplished in accordance with procedures in Disaster Control (Ashore and Afloat), NavPers 10899-A, chapter 7.

INSECT AND RODENT CONTROL

There are many kinds of galley pests, but the most common are flies, roaches, and mice (rarely rats). Great losses result from insect and rodent damage to subsistence and many other items of property in the absence of effective control programs.

Your commanding officer will set up such programs for the entire activity, but this does not relieve you of the responsibility for seeing that precautions are carried out for insect and rodent control in galley spaces. The best control measures for insects and rodents are proper cleaning of galley spaces and the proper collection and disposal of all garbage. Mice will not live where they cannot get food. Roaches also are and indication of insanitary conditions. Such insects will come aboard in crates of food, so that continual high sanitation standards must be maintained.

To make certain none of the commonly known insects and rodents contaminate food, utensils, and dishes, you must maintain constant vigilance and also observe the following rules:

1. Keep all galley spaces clean.
2. Clean up spilled foods immediately.
3. Be sure to thaw meat in the thaw box—never in the passageway or on the meat block.
4. Cover all foods that are not actually being prepared.
5. Leave no food exposed overnight.
6. Keep equipment clean and germ-free.
7. Remove all crumbs and food particles at the end of each meal.
8. Dispose of all garbage, rubbish, and litter promptly.
9. Keep garbage cans covered tightly; empty, wash, and scald them regularly.
10. Kill flies and roaches with sprays and powders.
11. Use traps for catching rats and mice.

When routine sanitary measures are not effective to control or eliminate insects and rodents, notify your medical officer or Medical Department representative immediately. He will advise you concerning the use of more drastic, corrective action.

If you are given insect poisons to use in your galley spaces, you must take every precaution, if they cannot be used immediately, to stow them so that they will not be mistaken for baking powder or other food items. Poison baits are often recommended to supplement rat and mouse trapping and other programs. They are effective in rodent control, but they must be used with all recommended safeguards, since they are also poisonous to human beings.

CHAPTER 9

MEAT

Meat appears on the Navy menu in some form, and in generaous quantity, each day. It is the focal point of every meal, often dictating what other dishes will be served. Meat affords excellent nutritional benefits, supplying calories, high-quality protein, iron, phosphorus, and essential vitamins, especially those of the "B" group. Correctly cooked and served, meat is indicative of a well informed and skillful Commissaryman.

Figure 9-1.—Beef chart.

CARCASS BEEF

Beef is the most frequently used of all meats. By carefully studying the beef chart (fig. 9-1), you will become familiar with the locations, structure, and names of bones. The line A—B shows where the side is divided.

Figure 9-2 shows a hindquarter divided into various sections which you should be able to recognize. Dotted lines indicate pieces that are cut from the opposite side of the quarter. Cuts numbered 4 through 9 are used for roasts and steaks; cuts numbered 1, 2, 3, and 10 are used for braising, stewing, or grinding.

Figure 9-2.—Beef hindquarter.

Figure 9-3 shows the names and locations of the cuts that are made from the beef forequarter. Cuts numbered 1, 3, 4, 7, and 8 are used for roasts and steaks. Cuts numbered 2, 5, 6, and 9 are used for braising, stewing, or grinding.

8581

Figure 9-3.—Beef forequarter. 48.39

BONELESS BEEF

Boneless beef is carcass beef cut according to specifications for the Armed Forces. The meat is cut, wrapped, and packed in fiberboard boxes, then frozen. The boxes of beef weigh approximately 50 pounds. Bones, excess fat, gristle, and tendons are removed in the processing plants. The beef is issued in six categories as shown in table 9-1.

VEAL

Veal is best defined as immature beef or calves of less than 1 year of age. Most of the veal or calves slaughtered for meat are dairy cattle. The younger animals of other cattle breeds are allowed to mature for beef. The bone structure is identical to beef, although bone sizes are quite different, the animal for veal being much smaller.

Veal is cut from veal sides in the order shown in figure 9-4. One of the most popular uses of veal is for cutlets. Roasts may be used for this purpose, including the beal boneless or bone-in, illustrated in figure 9-5.

Navy general messes use fabricated veal categories and cuts in semiboneless and boneless form. Boneless consists of two categories, cutlets and flaked steaks. Semiboneless is made up of chops, roasts, and stews. Chops are cut from veal back, tenderloin butt, and knuckle. For roasts, the top round, buttom round, clod, and

Table 9-1.—Portion-cut Six-way Beef Categories and Cuts

Category	Percent of Unit	Description of Cut
Portion-cut Grill Steaks	13.50 minimum	Weight: $6\frac{1}{4}$ to $7\frac{1}{2}$ oz. Includes: Ribeye, loin strip, sirloin butt, tenderloin cuts (percent quantities of each decreases in order named).
Oven Roasts	16.50 minimum	Includes: Top round, knuckle, sirloin rump, eye of round (percent quantity decreases in order named).
Portion-cut Swiss Steaks	10.0 minimum	Weight: $5\frac{1}{4}$ to $6\frac{3}{4}$ oz steaks, mechanically tenderized, whole units of less tender cuts.
Pot Roasts	15.0 minimum	Includes: Cold, chuck roll, brisket, heel, plus other cuts (percent quantity decreases in order named).
Diced Meat	11.0 maximum or 9.0 minimum	Each piece measures: Not greater than 3 in. nor less than $\frac{1}{2}$ in. along longest surface and weighs 2 oz maximum (with a 10 percent deviation allowance per lot).
Ground Meat	34.0 maximum	Fat content: A single lot may contain up to 25.0 percent by analysis, provided that the average for the contract (on weight basis) does not exceed 22.0 percent fat by analysis.

sirloin-rump butt are used. The shoulder, neck, and brisket are used for stews.

LAMB

Lamb is issued to the Navy general messes as frozen carcass, leg frozen, or frozen telescope. Carcasses are divided into primal cuts for the retail trade as shown in figure 9-6.

The major use of lamb in the Navy general mess is for chops. See figure 9-7.

PORK

Pork used by the Navy is in the forms of boston butt, loin (bladeless, boneless, string tied, tenderloin), spareribs, hams, and bacon. Pork cuts are procured both in the fresh and the cured state. Figure 9-8 shows the names and locations of the bones of a pork carcass.

Boston Butt

The boston butt cut is that portion of the skinned pork shoulder remaining after the picnic ham has been removed. See figure 9-9. This cut has the major portion of the bladebone still remaining, but the underlying excess of fat has been removed. This form of pork cut is not cured or smoked, but is used for preparing a number of meat dishes where moist heat is employed.

Loin

Loins are the choicest cuts of pork. They are used for roast pork and for chops prepared in a variety of ways, including both moist and dry heat methods.

Bladeless.—This is that portion of the loin remaining after the removal of the bladebone and related cartilage.

Boneless, String-Tied.—This is a completely boned item with tenderloin, cartilages, and rib figures removed.

Tenderloin.—This is a muscle removed from the loin section of pork sides. The tenderloin is relatively small in size. The use of this item is limited to a very few general messes.

Cutting the Loin

The steps necessary to complete boning of a pork loin from which the bladebone has been removed are shown in figure 9-10 on page 132.

Whole pork loins may be used for roasting if divided into two pieces of equal lengths; the pieces boned and string tied, or kept separate for roasting. See figure 9-11 on page 133.

The loin is used for roasting or is cut into pork chops with bones or without bones as illustrated in figures 9-12 and 9-13 on pages 134 and 135.

Spare Ribs

Spareribs are a bony but flavorful section of a pork side, made by separating the rib bones closely from the backbone and loin strip. See figure 9-9 on page 131.

Figure 9-6.—Main cuts of lamb.

1 - ARM CHOPS. CUT UNSPLIT SHOULDERS AS SHOWN.

2 - BLADE CHOPS. CUT FROM UNSPLIT SHOULDERS AND THEN DIVIDE EACH CHOP INTO TWO PIECES. REMOVE CHINE AND FEATHER BONES.

3 - RIB CHOPS FROM LAMB RACKS (SPLIT). REMOVE BACKBONE AS SHOWN AT LEFT. LOWER RIGHT--RIB CHOPS WITH FELL; UPPER RIGHT-FRENCHED RIB CHOPS.

4 - LOIN CHOPS. SPLIT LOIN AS SHOWN UPPER LEFT, AFTER REMOVING FLANK, FELL, AND EXCESS FAT. LEAVE LOIN UNSPLIT FOR DOUBLE CHOPS.

5 - SIRLOIN CHOPS. CUT LEG (SIRLOIN SECTION) AS SHOWN.

6 - TYPES OF CHOPS FROM LEG. LEFT-LEG; CENTER-SIRLOIN; RIGHT-PINBONE.

8585

Figure 9-8.—Pork chart.

8586

Figure 9-9.—Wholesale cuts of pork. 48.94

Bacon

Bacon is available for general mess use in several forms. The type of cure used on slab sliced and canned bacon varies according to the packer contract. For example, one type of cure is dry sugar-box or dry box cured. With process dry salt, sugar (an optional ingredient), nitrates, nitrites, and the spices are rubbed into the bacon. If sugar is used, the cure is referred to as dry sugar-box cure. The slices are packed in a box covered with a slatted lid so it can cure, hence the expression "box cure." The curing period covers 3 to 4 weeks, during which time moisture is withdrawn from the bacon as the salt is applied.

Ham

Canned whole ham and boneless frozen ham are used in Navy general messes.

Pear-shaped canned whole boneless ham (whole or partial) is perishable and must be stowed under refrigeration to maintain flavor and quality. It is precooked, but a thorough heating and glazing will enrich its flavor. Precooked, frozen boneless casing type hams average 9 pounds each and can vary from 8 to 12 pounds each. These hams are heated to an internal temperature of at least 150°F. The precooked frozen boneless hams are SMOKED, a treatment used on most cured meats to add color and flavor. An 18-hour smoke period is required for precooked hams.

Slicing Canned Ham

Whole cooked hams, packed in pear-shaped cans have high yield, ease of use, and economy. The full measure of these benefits is never reaped, however, if canned ham is improperly sliced. Uneven portions are wasteful and costly, besides being unattractive to serve.

The following machine slicing technique is recommended to obtain the maximum number of usable slices from either whole canned ham after baking or as it comes from the can for grilling.

As shown in figure 9-14 on page 135, the whole ham is first divided into three sections. The upper third section is cut straight across the butt end, and the remaining portion is halved into two even pieces lengthwise.

The slices are cut lengthwise across the butt section as well as the other sections as shown. Cutting with the grain of the butt section, as illustrated, is contrary to the general rule of meat carving: that is, meat should be carved across the grain to shorten lengthy muscle fibers and tenderize. Canned hams, however, are already tender products because of the process used; hence, they become another exception to the cross-grain carving rule. Cut the canned ham as directed to get the highest yield per ham.

THAWING METHODS FOR FROZEN MEATS

Frozen meat may be thawed in several ways. The preferred method is slow thawing because there is less drip loss in the meat. Meat thawed slowly yields a juicier and more palatable cooked product. An alternate method is recommended under circumstances where slow thawing is not practicable, such as on small ships with limited chill space, or whenever time is limited between meat issue and meat time. Once meat

8288 8587

1 - LOOSEN THE BACKBONE BY SAWING ACROSS BASE OF RIBS AT A SLIGHT ANGLE SO THAT THE SAW BLADE WILL NOT CUT INTO THE "EYE" OF THE LOIN.

2 - REMOVE BACKBONE, LEAVING NO MORE MEAT THAN NECESSARY ON THIS BONE.

3 - LIFT BACKRIBS FROM MEAT. THE BONELESS BLADE LOIN IS USED FOR (1) ROAST AS INDIVIDUAL LOINS OR TWO TIED TOGETHER AS A BONELESS ROLL; AND (2) CHOPS AS SINGLE SLICES, OR BUTTERFLY CUTS.

has been defrosted or thawed, it should be used as soon as possible, and not refrozen. Breakouts should not exceed the amount to be served.

Preferred Thawing Procedure

Break out the quantity of meat required. Remove from shipping container, but leave inside wrappings on the meat. Thaw slowly at reefer temperatures (36°-38°F) until almost completely thawed. The thawing period will vary according to:

1. Size of the meat cut. The larger the size, the longer time required.
2. Bone-in or boneless state. Bone-in meat takes less time to thaw.
3. Air temperature and circulation in chill space. Moving air accelerates thawing.
4. Quantity of meat being thawed in a given area. A large amount will lower the temperature of the room and deter thawing action. Spread the cuts out. Do not stack them.

It is almost impossible to predict exact time required to thaw meat unless there is a perfectly controlled set of circumstances. Frozen wholesale beef cuts and frozen boneless beef may require up to 48 hours to thaw at 36°-38°F temperatures; however, veal sides and telescope lamb may thaw in about 36 hours at this temperature range. Cuts from pork, veal, and lamb would probably thaw in about 24 hours under refrigerator temperatures.

Alternate Thawing Procedure

If it is necessary to thaw the frozen meat quickly, thaw it in the original sealed container at room temperature (72°F or above) for a period of several hours. Then, open the box. If the meat is not completely thawed, it will become so rapidly. The important point to remember is that unsealed boxes of the various six-way beef components, for example, will be the equivalent of a refrigerator, allowing meat to thaw slowly. The thawing continues inwardly toward the center of the package. Meanwhile, the outside thawed pieces will remain sufficiently cold to prevent spoilage while the center is thawing.

CHAPTER 10

FOOD PREPARATION

Food is your business. This chapter covers some of the what, how, why, and when of food preparation.

There is a short phrase that expresses the vital importance of your job as Commissaryman—men must eat to live. How the men of your ship will eat depends on you. Remember that the desired end result of all your functions as a Commissaryman is for the food to be accepted by the men on the mess line. To achieve this, you must continually strive for perfection in providing palatable, wholesome, and attractive food. You can get a great deal of satisfaction from serving an excellent meal, and your diligence, zeal, and attention to detail in preparing food can do much to keep the morale high and the crew happy.

To ensure efficient day-to-day operations of the general mess, the senior Commissaryman uses management tools which provide guidance for the men assigned to the galley. These tools are explained so that you will have a clear understanding of why they are used and how they serve to promote efficiency in the galley.

FOOD PREPARATION WORKSHEET

The Food Preparation Worksheet (NavSandA Form 1090) is an important part of food preparation. When posted in the galley, it becomes a written directive—a medium for passing information from supervisory personnel to watch captains and other key general mess personnel. See figure 10-1.

Study the Food Preparation Worksheet when you are on watch; it provides pertinent information concerning the preparation of the daily menu. The menu item column is copied directly from the approved General Mess Menu (NavSandA Form 1080). Observe figure 10-1; notice that space is provided for the Navy-Marine Corps Recipe Card number to be used and the portions to be prepared. Space is also provided for any additional instructions from the senior Commissaryman regarding the preparation and serving of a menu item.

The Food Preparation Worksheet is a valuable record of the menu for the day. Meaningful information which is a "must know" for any person supervising a general mess operation can be posted on it. Such information includes the number of persons actually fed and the acceptability of specific menu items. All this information is beneficial when the senior Commissaryman prepares future Food Preparation Worksheets.

STANDARDIZED RECIPES

All food for the general mess should be prepared according to the recipes published in the Navy-Marine Corps Recipe Service or recipes which have been approved by the commanding officer.

The Navy-Marine Corps Recipe Service consists of over 700 recipes which have been developed specifically for use in the general mess. The recipes are standardized to yield 100 portions and have been pretested in Navy test galleys as well as aboard ship, and reviewed by the Food Advisory Committee of the National Security Industrial Association.

The use of standardized recipes ensures quality food preparation by allowing more time for skill and finesse in preparing, serving, and merchandizing food. Variations in quality and quantity do not occur because guesswork is eliminated. Exact amounts of the various subsistence items required by a menu and accurate yields prevent leftovers and promote food cost control. Subsistence items for the day's menu can be drawn from the issueroom and accurately posted to the daily S. and A. Form 1059-1.

Recipes in the Navy-Marine Corps Recipe Service are printed on 5" by 8" cards. The yield for each recipe is given in weight and

8592

amount or both in the upper left corner. The size of the individual portion appears in the upper right corner. The ingredients are designated in weights, measures, or both. The measure specified for each ingredient is comparable to its weight. More accurate results can be expected when the ingredients are weighed instead of measured.

The amounts (measures) of ingredients are designated in teaspoons, tablespoons, cups, pints, quarts, and gallons. Listed below are the abbreviations used on the recipe cards; equivalents of weights and measures; and sizes of scoops or dippers:

Abbreviations Used on Recipe Cards

A.P.	= as purchased
E.P.	= edible portion
t or tsp	= teaspoon
T or tbsp	= tablespoon
C	= cup
pt	= pint
qt	= quart
gal	= gallon
oz	= ounce
lb	= pound

Equivalents of Weights and Measures

3 teaspoons	= 1 tablespoon
16 tablespoons	= 1 cup
1 cup	= $^1/_2$ pint
2 cups	= 1 pint
2 pints	= 1 quart
4 quarts	= 1 gallon
8 quarts dry	= 1 peck
4 pecks	= 1 bushel
16 ounces	= 1 pound
32 fluid ounces	= 1 fluid quart

Sizes of Scoops or Dippers

No. Per Quart	Measure	Approximate Weight
30	$^1/_8$ cup (2 tbsp)	1 ounce
16	$^1/_4$ cup (4 tbsp)	2 ounces
12	$^1/_3$ cup (5 tbsp)	$2^1/_2$ ounces
10	$^2/_5$ cup ($6^2/_3$ tbsp)	$3^1/_2$ to 4 ounces
8	$^1/_2$ cup (8 tbsp)	4 ounces

Steps in Using Standardized Recipes

There are five steps which you must follow when you are using standardized recipes, if an acceptable, uniform end-product is to be prepared. These steps are as follows:

1. Know the number of servings you are to prepare. Refer to the Food Preparation Worksheet for this information.

2. Read the recipe all the way through. By carefully reading the recipe, you will know what ingredients are needed, the quantity of each, and the method to be followed in preparation.

3. Adjust the recipe, which will yield 100 servings, to the number of servings you are to prepare. Let us assume that the Food Preparation Worksheet calls for 348 servings.

You will need a working factor—and this factor is obtained by dividing the number of servings needed by 100. In this instance, 348 divided by 100 equals a 3.48 working factor. The quantity of each ingredient in the recipe is multiplied by the working factor.

If, for example, you are going to adjust the recipe for beef loaf J-42 (fig. 10-2) to yield 348 servings, the quantity of bread, onion, and green pepper listed would be changed as follows:

a. The weight of each ingredient as listed on the recipe is multiplied by the working factor.

Bread, dry	Green Peppers
4 lb	.50 lb
x 3.48	x 3.48
13.92 lb	1.7400 lb

Onions

```
  1.25 lb
x 3.48
  1000
  500
 375
4.3500 lb
```

b. The part of a pound, as the .92 pound of bread, dry; .35 pound of onions; or .74 pound of green peppers, is converted to ounces by multiplying 16 by the decimal.

```
   16                16 ounces
 .92 lb bread        .35 lb onions
   32                80
 144                 48
14.72                5.60 ounces
```

PORT WATCH CAPTAIN R.C. Jones, CS1 STBD. WATCH CAPTAIN R. White CS1

COMMISSARYMAN 3 & 2

GUIDELINES FOR PREPARATION AND USE OF FOOD PREPARATION WORKSHEET

The senior Commissaryman prepares the Food Preparation Worksheet; watch captains review and sign the worksheet before it is posted to indicate understanding and concurrence.

It is suggested that the format be posted on clipboard (7520-254-4610 measuring 9 by 15 inches). When posted on this clipboard and hung in the galley, the form is readily available for reference by Commissaryman when he is making his "check rounds."

The worksheet may be filed in legal-size manilla folders (9 x $14^{3}/_{4}$ inches).

48.99.1

138 8594

RECIPE CARD

Standard Navy-Marine Corps Recipe Card number or locally approved recipe.

MENU ITEM

List the menu items to be prepared indicating any leftover foods that are to be served with the meal. Do not include such items as crackers, assorted breads, jelly, jam, milk, coffee, etc. A pattern for service of these items should be developed at each activity and posted in the galley or serving counter area.

PORTIONS TO PREPARE

The number of portions is determined by the predicted number to be fed or the acceptability of the menu item.

INSTRUCTIONS

Special instructions regarding the preparation and/or service of menu items and the service of leftover food to be served with the meal are to be entered. To say "follow the recipe card" is not necessary; the recipe card number in the first column indicates that the recipe will be followed. An example of an instruction would be "use dehydrated onions in Step 3" or "slice meat loaf on the line."

START PREPARATION

Quality food preparation requires time and attention to detail. Menu items to be prepared, sanitary precautions, and the number of men to do the work, determine the time for precooking preparation.

START COOKING

The length of time required to cook a menu item (first batch), and the scheduled meal hour, determine the time actual cooking should begin. It should be timed so that the menu item can be transferred to the serving counter for immediate service.

NUMBER OF BATCHES

Every effort should be made to practice small-batch or progressive cookery. The number of batches, and quantity per batch, is determined by the total number of portions to prepare, the length of the serving hour, and peak periods.

Figure 10-1.—Food Preparation Worksheet. 48.99.2

GUIDELINES FOR PREPARATION AND USE OF FOOD PREPARATION WORKSHEET—
Continued

VEGETABLE PREPARATION

The vegetable, quantity, method of preparation (diced, sliced, etc.), and the hour the preparation should be accomplished should be entered. Any additional quantities used should also be entered by the spud coxswain. At the end of the day, the spud coxswain should sign to indicate all has been accomplished per instructions.

BAKE SHOP

The number of portions of any dessert item and hot breads should be entered. Note any special instructions for time, portion size, garnish, cutting and serving. Any additional items issued to serving line or for use in bake shop should be entered, and any leftover dessert items returned after a meal serving hour. At the end of the day the baker should sign to indicate that all has been accomplished per instructions.

MEAT ROOM

List the meat items, quantity, and any specific instructions for the Commissaryman assigned to the meat room or for the watch captain. Weekly menu should be reviewed when this section is being completed so that frozen meat items scheduled for meals 2 or 3 days in the future, can be removed from the freeze space to chill space to allow for proper thawing. Quantities of meat items needed during a serving period, in addition to those listed, should be noted. Responsible Commissaryman or watch captain should sign at end of day's work.

AFTER THE MEAL HAS BEEN SERVED

Watch captain:

1. Posts the number of persons actually fed (obtain this information from MAA).
2. Completes the "Portions Leftover" column.

SENIOR COMMISSARYMAN AND/OR WATCH CAPTAIN

Completes the "Comments" column indicating the acceptability of new items and the course of action to be taken in regard to leftover food, noting reason for portions short, or for preparation in excess; acceptability of menu items.

Figure 10-1.—Food Preparation Worksheet—Continued.

48.99.4

8597

BEEF LOAF

J. MEAT No. 42

YIELD: 100 Portions (8 Loaves) — EACH PORTION: 1 Slice

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Bread, dry	4 lb	2 gal		1. Moisten bread with water; press out and discard excess water.
Water		To moisten		
Onions, finely chopped	1¼ lb	1 qt		2. Sauté vegetables in hot, melted shortening until light brown.
Peppers, green, finely chopped	½ lb	¼ qt		
Celery, finely chopped	1 lb	¾ qt		
Shortening	7 oz	1 cup		
Beef, boneless, ground	29 lb			3. Combine moistened bread, sautéed vegetables, ground beef, eggs, salt, and pepper. Mix thoroughly but lightly. Avoid overmixing, if using a mixer.
Eggs, whole, beaten	1 lb 3 oz	12 eggs (1¼ pt)		
Salt	6 oz	10 tbsp		
Pepper	½ oz	2 tbsp		
Water (variable)		3 cups		4. Add water only if necessary. 5. Shape into 5¼ lb loaves in lightly greased roasting pans (18 by 24 inches). 6. Bake at 325° F until done, approximately 1½ hours. Drain off excess fat.

NOTE: 1. Cut 13 slices per loaf.

2. Dehydrated sliced onions and dehydrated green peppers may be used in Step 2. Reconstitute according to instructions on Recipe Cards A–11 and A–12.

VARIATIONS

1. VEAL LOAF: Omit green peppers; use 20 lb of ground veal and 10 lb of ground beef.
2. PORK LOAF: Omit green peppers; use 15 lb ground lean pork and 15 lb of ground beef.
3. VEGETABLE MEAT LOAF: Add 1 lb of carrots to vegetables, and 2 cups of catsup to meat mixture. Pour 1½ qt tomato juice over meat loaf before baking.

48.47.1

Figure 10-2.—Recipe for beef loaf.

16 ounces
.74 lb green peppers
64
112
11.84

c. After the part of a pound has been converted to ounces, use the following scale to ROUND them off.

.01 to .12 = 0.

.13 to .37 = 0.25 or $^1/_4$ ounce

.38 to .67 = 0.50 or $^1/_2$ ounce

.68 to .87 = 0.75 or $^3/_4$ ounce

.88 to .99 = 0.99 or 1 ounce

According to the scale,

14.72 ounces of bread will be rounded to $14^3/_4$ ounces

5.60 ounces of onions will be rounded to $5^1/_2$ ounces

11.84 ounces of green peppers will be rounded to $11^3/_4$ ounces.

Going back to the original calculation: 13.92 pounds of bread, dry, will be 13 pounds $14^3/_4$ ounces; 4.35 pounds of onions will be 4 pounds $5^1/_2$ ounces; and 1.74 pounds of green peppers will be 1 pound $11^3/_4$ ounces.

If you decide to use the volume measures which are listed on each recipe, instead of the weights, the same procedure is used; 3.75 cups of onions times 3.48 equals 13.05 cups. The part of the cup must be changed to teaspoons or tablespoons so you multiply 16 tbsp per cup times .05 and you get .80 or $^3/_4$ tablespoon.

On occasions you may have to adjust the recipe on the basis of the amount of ingredients available rather than for the number of servings. When you increase the quantity of each ingredient in the recipe to yield 348 servings, you will need 100.92 pounds (29 pounds times 3.48) of beef. But you have been issued 99 pounds and are instructed to use that amount of meat. Knowing that the proportion of all ingredients in the recipe must be in balance to ensure an acceptable end-product, you again calculate a working factor. This is done by dividing the pounds you have to use by the pounds required to yield 100 servings.

For example, 99 pounds divided by 29 (pounds per 100 servings) equals a 3.41 working factor. The quantity of each item in the recipe will be multiplied by 3.41.

4. Before you start to prepare the recipe, assemble all of the necessary ingredients, the measures or scale, the mixing spoons or beaters, the right size pan, and the number of pans you will need.

5. Place the recipe so that as you work, you can follow each step as it is written on the recipe card. Then carefully and accurately do each step. Remember, there are no shortcuts.

SANITARY ASPECTS OF FOOD PREPARATION

Every precaution should be taken to handle food under proper sanitary conditions to prevent contamination.

The following paragraphs discuss certain procedures that should be followed when you are preparing food.

Safe Holding Temperatures for Cooked Foods

Protein foods which are not served immediately after cooking should be either chilled to temperatures of 40°F or lower (but not frozen) or held at 140°F or higher. Protein foods include meats, fish, poultry, gravies, meat stocks, soups, eggs, custards, cream fillings, and milk.

Cooked protein foods which have been held at temperatures between 40°F and 140°F for more than 3 hours should be considered unsafe for consumption and destroyed. If foods are refrigerated at intervals and then permitted to warm up, the total time of the various periods between 40°F and 140°F should not exceed 3 hours. Protein foods that are composed of ingredients which are hand-peeled, hand-sliced, or hand-diced after cooking should never be used as leftovers; the 3-hour limit between temperatures of 40°F and 140°F is usually taken in preparing, chilling, and serving the food. Hand preparation not only increases the chance of contamination, but generally increases the length of time that these foods are held at room temperatures.

You should not return opened jars or bowls of mayonnaise and cooked salad dressing from salad bars to refrigerators for re-use at a later meal, because of the danger of miscalculation of total lapsed time that these salad dressings have been held at temperatures between 40°F and 140°F. Instead, mayonnaise and cooked salad dressings should be placed on the salad bar in small quantities, and should not be returned from the salad bar for re-use.

8599

Leftovers to be Chilled

When leftovers or warm foods are chilled, care should be taken to assure prompt and thorough chilling (40°F or below) to the center of the food mass. Foods that are to be refrigerated should be placed in shallow pans to a depth of not more than 3 inches and should be covered with lids or waxed paper. Such foods should not be put in large deep pans, as chilling may take so long to get to the center of the food mass that sufficient time is allowed for growth of harmful bacteria and the development of toxin. Guard against any other procedures which may delay the cooling of the food. Place food to be chilled in the refrigerator immediately. Do not save leftovers for more than 36 hours. Freezing leftovers is prohibited.

Ground Food

Refrigerate immediately food which has been ground or chopped if it is going to be cooked later or incorporated in a made-dish. Such ground or chopped food should be refrigerated in shallow pans filled to a depth of not more than 3 inches. Cover the food until it is ready for cooking.

Meats

Meats which are cut, sliced, or diced should be placed in shallow containers, covered with lids or waxed paper, and refrigerated immediately. The temperature of the meat cutting room should be maintained at 50°F to 60°F, if possible.

Reconstituted Dehydrated Foods

Foods such as reconstituted dried eggs and vegetables, are as susceptible to spoilage after reconstitution as the fresh items. After dehydrated foods have been reconstituted, they should not be allowed to remain at room temperature more than 3 hours from the time the water is added.

SOUPS

Soup is a tasty, popular food. It is nutritious and wholesome and stimulates the appetite. Soup should be served at least once a day in cold weather, if practicable, and at least every few days regardless of the weather.

Kinds of Soups

Soups are basically of two kinds; thin or clear soups (light) and thick or hearty soups (heavy). The thin or clear soup is usually served before a heavy meal. The heavy soup is served with a light meal and may be sufficiently heavy to constitute the main dish of such a meal.

Broth and consomme are examples of light soups and are made from basic soup stock. Broth is made from stock using only one type of meat, and consomme is made from a very strong, clear stock from one or more types of meat, plus vegetables. Vegetable soup, celery soup, onion soup, and rice soup are other examples of light soups. No thickening agent is added to the light soup.

The hearty or heavy soups are: (1) those that are thickened with flour or cereals such as barley, rice, or macaroni; (2) cream soups and chowders made from either a stock base to which hot milk is added or from a thin white sauce, and (3) purees, made from cooked peas, beans, or cooked fresh vegetables which are put through a sieve and then added to a seasoned stock.

Soup Stock

Meat stock is made by using bones (beef, ham, veal, or lamb) which have been sawed not over 6 inches in length. The sawed bones, small pieces of less tender cuts of meat, and vegetables are placed in a steam-jacketed kettle, covered with cold water (liquids from canned cooked vegetables may be used), and allowed to simmer slowly for 6 hours. The stock is then strained from the solids and is ready to form the basis of whatever type of soup is to be prepared.

During the simmering period, the bones and meat should be kept submerged in liquid. In this period, the meat gives off fat which rises to the surface. When the stock is thoroughly cooked the fat may be removed by: (1) placing a lettuce leaf in the hot stock—to be removed when the leaf has absorbed the fat; or (2) placing the stock in the refrigerator to chill. The fat forms a thin layer on top of the stock and is easily removed with a skimmer.

The P (soups) section of the Navy-Marine Corps Recipe Service contains recipes for various kinds of meat and chicken stock. The ration dense items, instant beef soup and gravy base, and instant chicken soup and gravy base, may be reconstituted for use in any soup recipe.

8600

These powdered bases are seasoned and when reconstituted in boiling water have the characteristic flavor of beef broth or chicken broth. The proportions to be used when reconstituting these bases are included in the A (miscellaneous) section of the recipe service.

Soup stock spoils easily—HANDLE IT CAREFULLY. It should be placed in a clean container, covered securely with the container lid, and stored in the refrigerator until ready to use. Make it fresh every day.

Vegetables for Soup

The vegetables most commonly used for soups are celery, carrots, beans, peas, green peppers, onions, tomatoes, and okra. Cut the vegetables into small cubes, or into match like strips called julienne; cook each vegetable separately until it is tender, using as little water as possible. Then add both the solids and the cooking liquids to the stock. This cooking liquid contains valuable vitamins as well as some of the flavor of the vegetable.

The dehydrated vegetables such as parsley, onions, and potatoes may be used in soups. It is not necessary to reconstitute them first; they may be added directly to the soup stock.

Ration-Dense Soups

The canned dehydrated soups and condensed soups are not only easy to prepare but they are timesavers and space savers.

Dehydrated soups such as chicken-noodle, green pea, and tomato-vegetable are prepared by adding the required amount of the dehydrated soup to a proportionate quantity of boiling water. The mixture is covered and allowed to simmer for the length of time specified on the container. The product closely approximates in appearance and flavor the same type of soup made from raw food items.

The canned condensed soups are reconstituted by using an equal volume of cold water, which is stirred in slowly. A wire whip is a good utensil to use for stirring this mixture. The soup is brought to a boil and is then ready to serve. Condensed soups have the characteristic good body, aroma, flavor, color, and consistency of the particular style and type of soup.

Seasoning Soups

The individual recipe in the soup section specifies the types and amounts of seasonings to be used. When making meat or chicken stock, the flavor from the ingredients used concentrates; therefore, accurate measures of spices or herbs to be added are essential. Just before the soup is to be served, check it again for proper seasoning. It is better to add more seasoning, of suitable types, to the stock or soup a short time before serving, rather than have a soup so highly seasoned it is unpalatable. If the taste-check indicates that the soup is too salty, add a few slices of raw potatoes, bring the soup to a simmer for a few minutes, then remove the potatoes.

MEAT COOKERY

Meat is by far the most popular food in the mess, and it is the most expensive. Because of its nutritional excellence in food values, notably protein, it is not surprising that meat in some variety and form appears in the menu, and in generous quantity, almost every meal. Meat, correctly cooked and served, indicates that it was prepared by a well-informed and skillful Commissaryman.

Cooking Methods

Meat cuts are cooked by (1) dry heat, (2) moist heat, and (3) frying. The tender cuts of meat are cooked by dry heat because they contain little connective tissue. Moist heat is required to make tender those cuts which contain much connective muscle tissue. Various treatments before cooking have been recommended for tenderizing meat. Grinding, cubing, slicing, and pounding break up the muscle and connective tissue and make meat tender.

The dry heat methods are (1) roasting, (2) broiling, (3) pan-broiling or griddle-broiling. The moist heat methods are (1) braising and (2) cooking in liquid. The frying methods are (1) panfrying or sauteeing and (2) deep-fat frying.

Dry Heat Methods

The dry heat methods most frequently used in Navy general messes for cooking the tender cuts of meat are roasting and griddle-broiling.

ROASTING is synonymous with "baking," but baking is seldom used when speaking of meat cookery, except in the case of ham. Roasting may be defined as cooking by dry heat in the oven.

The following rules of roasting apply to beef, veal, pork, and lamb. Included with each rule is the "why."

8601
4008

1. A moderately low oven temperature (250° F to 350° F) should be used because at this temperature (1) the roast is uniformly done throughout; (2) the cooking losses are moderate; (3) the meat is more palatable; and (4) the roast is plump and full. High temperatures cause excessive shrinkage, uneven cooking, and decreased juiciness. (See fig. 10-3.)

Figure 10-3.—High temperature vs low temperature roasting.

2. Searing does not keep in juices but actually increases the cooking losses. Searing causes loss of fat and contributes to excessive shrinkage.

3. Meat should be roasted fat side up, thus eliminating basting. Place the roast fat side up in the pan because as the meat cooks, it will baste itself with the melting fat.

4. A roast may be salted before or after cooking. Salt penetrates less than half an inch below the surface and any salt added before cooking adds flavoring to the drippings.

5. A roast should never be covered. Cook uncovered. If the roasting pan is covered, the moisture escaping from the meat will surround it and the meat will be cooked by moist heat.

6. Water should not be added. Roasts cooked without added water are juicer and more flavorful. The only reason for adding water would be to keep the drippings from becoming overly brown which does not happen when low oven temperatures are used.

7. Flouring a roast is not necessary. Drippings from a floured roast may be a more attractive brown, but the same results are obtained by browning flour in the drippings when making gravy.

8. A meat thermometer is the only accurate means of telling when a roast is done. The length of cooking time depends on the temperature of the oven, the weight and shape of the roast, and the kind of meat. See figure 10-4.

The thermometer should be inserted into the center of the main muscle (the thickest meat part) so that the tip is away from the bone and fat. As the heat from the oven penetrates the meat, the temperature at the center gradually rises and this rise is registered on the thermometer. When the thermometer registers the internal temperature which indicates doneness for that particular kind of meat, the roast is ready to be removed from the oven. The guidance card in the J (meat) section of the recipe service J-G-1 indicates the correct internal temperature which should be reached when roasting the various types of meat.

Boneless meat will require somewhat longer cooking than meat with bones. A smaller roast requires more minutes per pound than a large

CAUTION: Using thermometer in oven above 400° F is not recommended.

1. The roasting temperatures indicated on the thermometer are approved by the National Live Stock and Meat Board and Poultry and Egg Board (National).

2. Insert thermometer at least 2 1/2 inches into thickest part of meat at an angle such that dial is easily readable when door is opened. The point should be in the center of the largest muscle, away from contact with bone, gristle or fat.

48.49

Figure 10-4.—Dial type roast meat thermometer.

8602

one. A lean roast requires less time than a fat one. The cuts of meat which may be roasted are listed in table 10-1.

In GRIDDLE-BROILING the heat is transmitted to the meat from the hot metal of the griddle. The meat is placed on an ungreased griddle and a moderate temperature is maintained which prevents the meat from overbrowning. Enough fat cooks out to keep the meat from sticking. Surplus fat should be removed as it collects, to prevent the meat from frying. The meat is turned occasionally to ensure even cooking. Tongs or a broad turner should be used,to turn the meat. Puncturing the meat with the tines of a fork allows the juices to escape with a resultant dry, coarse end-product.

The cuts of beef, lamb, and pork which may be griddle-broiled are listed in table 10-2. Pork chops and pork steaks, although tender, are never griddle-broiled. Pork requires thorough cooking to bring out its full flavor. Braised pork chops are more desirable from the standpoint of aroma, texture, tenderness, and flavor of the lean. Veal is not griddle-broiled because it is a lean meat and because of the abundance of connective tissue which requires long slow cooking.

When griddle-broiling meat, season one surface of the meat after it is browned, then the other side when you turn the meat.

Moist Heat Methods

Cooking meat by moist heat is done by two methods—braising and stewing. Each method is discussed in the following paragraphs.

Braising is used in the preparation of those cuts containing considerable connective tissue. To braise means to brown meat in a small amount of added fat, then to cover and cook slowly in juices from the meat or in a small amount of added liquid. The liquid may be water, stock, vegetable juices, thin sauces, or a combination of these liquids. The amount of liquid used is just enough to start the natural juices in meat. Only a small amount is added at a time as the color and appearance of both the meat and gravy are better if the liquid is kept to a minimum. Pot roast and swiss steak are examples of this method of moist heat cooking.

Cooking the less tender cuts long enough to make them tender causes some loss of meat flavor. Flavor is developed by dredging the pieces of meat in seasoned flour; then browning in a small amount of fat or by marinating the meat in a well-seasoned mixture of vinegar,

Table 10-1.—Meat Cuts Suitable For Oven Roasting (Dry Heat)

008603

vegetables, and spices. Sauerbraten, is an example of a less tender cut of meat that is marinated in a vinegar-spice mixture. The acid of the vinegar has a tenderizing effect on the connective tissue and the spice adds flavor. There is a theory that browning the meat develops flavor and aroma, and a rich brown color is typical of well-prepared braised dishes. Less tender cuts of meat may be scored (cutting the fibers) or pounded to break the connective tissue.

After the meat has been browned, the temperature is reduced, and cooking is continued at a low temperature so that the liquid will not boil. Braising may be done in the oven, on top of the range in a deep pot, or in the steam-jacketed kettle. Whichever means is used, the container must be tightly covered. The aim of braising is to produce a piece of meat which is evenly browned on the exterior, tender, juicy, and evenly cooked throughout, with no stringiness. Meat cuts which are braised are always cooked to the well-done stage.

The cuts of meat which may be braised are listed in table 10-3.

Cooking in Liquid

The second method of moist heat cooking is cooking in liquid. It is the method used in preparing the least tender cuts of meat. Small pieces of meat cooked in water are said to be STEWED; large pieces are said to be SIMMERED. In each case, the meat is covered with water and kept at a simmering temperature (185°F - 208°F). It is never boiled. Boiling the meat for the length of time required to tenderize it, would dissolve the connective tissue completely and the meat would fall apart, become stringy and dry.

Vegetables may or may not be added to the stew. If they are added, they are cooked to the just tender point, retaining their color and other characteristics. The gravy is light and smooth and of the typical flavor of the meat used in the stew. The pieces of meat may be dredged in seasoned flour and browned in a small amount of fat, or they may be browned, unfloured, before the liquid is added. The gravy will be a rich brown in color if the meat is browned first. Stews are made in a deep kettle which has a tight fitting lid and are held at the simmering temperature until the meat is done, usually $1\frac{1}{2}$ to 2 hours.

The cuts of meat used for stews are listed in table 10-4.

Cooking in liquid is used in the preparation of cured pork and beef cuts rather than fresh

Table 10-3.—Meat Cuts Cooked By Braising

8604

cuts. Fresh beef, if cooked in liquid, is more often braised because better flavor is developed and a more attractive appearance is obtained. Meat cooked in liquid is tender and juicy and holds its shape when sliced. Usually the steam-jacketed kettle is used so that the meat can be completely submerged in the liquid at all times.

The large cuts that are cooked in liquid are:

BEEF	PORK	VEAL
Fresh Neck Shank Plate Heel of round Brisket Shortribs Cured or corned Rump Brisket	Cured Whole ham Half ham Shoulder Picnic shoulder Boston butt Spareribs Fresh Spareribs	Neck Shank

Frying

SHALLOW FRYING is accomplished in a pan or on a griddle. This method of cooking is often called sauteing. Be sure the fat is hot before placing the meat in it, otherwise the meat will absorb too much of the fat and will be unappetizing. The terms "fry," "pan or griddle broil," and "braise" are frequently used interchangeably, or at least the distinction is not drawn finely. There is an inclination to say of any meat cooked in a frying pan or on a griddle that it is fried. For example, it is a common practice to brown certain cuts in a small amount of fat, then cover the pan, and continue to cook until the meat is tender, and call it frying. This of course is not frying at all, but braising, because when the pan is covered, the meat is surrounded by steam and the process is exactly the same as that used in cooking a pot-roast. In shallow frying, the meat is sometimes floured or breaded.

DEEP-FAT FRYING involves the complete covering of the meat with hot fat. Meat prepared in this manner should be breaded. To obtain the best results, the correct temperature of the fat must be known to prevent excess fat absorption or excessive browning of the exterior before the interior is cooked done. The only accurate means of knowing the temperature of the fat is to use a deep-fat thermometer.

Place just enough meat in the basket to cover the bottom of the basket, and lower it into the hot fat. The pieces to be fried should be of uniform size. Small pieces should usually be fried at a high temperature.

Cooking Frozen Meat

Most of the meat used in Navy general messes is procured as frozen meat and with the exception of a few cuts may be cooked in the frozen state. Hamburger, diced meat, and pork chops must be completely thawed before cooking.

In the frozen state, roasts will require approximately $^1/_3$ to $^1/_2$ additional cooking time. Seasoning, as well as flavoring, must be delayed until the outside is some what thawed and the surface is sufficiently moist to retain salt, pepper, and flour. The insertion of the meat thermometer can be delayed until the roasts are partially thawed.

Beef, veal, and lamb chops may be grilled in the frozen state. Pork chops MUST BE THAWED to ensure complete doneness. The lengthly periods required to cook any of these meats completely done from the frozen state make it less practical because it ties up the cook's time, as well as griddle space.

Grilling or deep-fat frying of slices of frozen liver of $^3/_8$ to $^1/_2$ inch thickness is recommended. Liver cooked without thawing is more moist and, therefore, more palatable than partially thawed cooked liver, and slices are more uniform and attractive in appearance.

POULTRY

Navy procurements of poultry are limited to ready-to-cook (eviscerated). This style greatly reduces storage space requirements.

Poultry is typed also according to its state of refrigeration: fresh, chilled, and frozen.

Thawing

Frozen chicken, turkeys, and ducks must be thawed before being prepared for cooking. Unlike thawing meat, no choice should be permitted in poultry thawing methods. All poultry must be thawed at refrigerator (36°F to 38°F) or chill temperatures. This rule applies to all market forms of frozen poultry: cut-up, quarters, halves, whole birds, or turkey rolls. Large turkeys (14 to 24 pounds or more) will require from 24 to 48 hours or more to thaw, depending upon the exact refrigerator or chill box temperature to which it is exposed and the amount of circulating air. DO NOT THAW POULTRY IN WATER.

0038605

Most whole turkeys and chickens come bagged in paper or plastic materials, and these may serve as wrappers to protect the poultry. Remove whole birds from the outer shipping containers and spread out for more rapid thawing. Loosen the inner bag, or wrapping material, to accelerate thawing, but do not remove it.

Layer-packs of cut-up chicken should be removed from the carton and spread out, but be sure to leave the inside sheets of wax paper (or other material that may be used for separating layers), to protect the surface of the chicken while thawing.

Frozen poultry that has been thawed should never be refrozen.

Use thawed frozen poultry as soon as possible. Do not hold in refrigeration (36°F - 38°F) over 24 hours. Poultry meat held in excess of 24 hours will not only have lowered quality but risks spoilage. Bacteria thrive on wet or moist surfaces and grow especially well in poultry.

Cleaning

Inspect all poultry after thawing for the presence of any spongy red lung tissue inside the back, loose membrane, pinfeathers, or skin defects; remove these, if present. Carcass turkeys, chickens, and ducks have necks and giblets wrapped and packed in the body cavity. Remove these, inspect, and rinse. Wash poultry inside and out under cold running water and drain.

Cooking Poultry

The fundamentals of cooking poultry do not differ from those applied to other meats. Dry-heat methods (frying, or roasting) are applicable to young, tender birds. Moist-heat methods (fricasseeing, simmering, steaming, or stewing) or a combination of moist and dry heat must be applied to older less-tender birds in order to make them tender and palatable. In moist-heat methods the water should simmer rather than boil to avoid the toughening effect of high temperature on the fibers. Depending upon the cooking method used, temperatures will vary, but slow to moderate temperatures are used at all times to develop maximum flavor, tenderness, color, and juiciness. Intense heat will harden and toughen the protein, shrink the muscles, and drive out the juices, thus producing a less palatable product.

All poultry should be cooked well done. To ensure this, each container of prepared chicken or turkey should be double checked.

Cooking losses will vary with the temperature and method of cooking and with the degree of fatness. Ducks have a lower yield of cooked meat and more fat than turkeys and chickens roasted at the same temperature. The yield of meat from chicken and turkey compares favorably with that from beef, pork, and lamb cuts with bone in.

When ROASTING poultry, precautions must be taken to prevent the poultry skin from becoming too hard and dry. An open pan should be used and a low oven temperature applied (250° to 350°F). A cloth moistened with melted fat is one means of preventing undesirable drying and toughening of the skin. As the cloth become dry, additional fat may be poured over it. The skin will then be brown and crisp but will carve well.

For even cooking, roast poultry with the breast side down through most of the cooking period, just turning it once, when about three-fourths done to develop the color of the breast. To turn the turkey, insert a meat fork into the neck cavity and a second meat fork into the body cavity. Then, lift the turkey and turn it breast side up. Roasting turkey in this manner ensures uniform cooking, and moist, flavorful meat. Pan drippings should be used for basting occasionally during the cooking period.

Turkey, being larger than most poultry, is more difficult to cook to the well-done stage without overdoing it. Care must be taken to cook it no longer than necessary; overcooking will result in loss of juices and stringy, dry meat. The meat thermometer inserted in the thickest part of the thigh muscle ensures proper roasting of the turkey. When the thermometer registers an internal temperature of 190°F, the turkey has reached the required stage of doneness. (See fig. 10-5 for the timetable for roasting unstuffed turkeys).

For PAN FRYING poultry, wipe the pieces dry. Then season them with salt and pepper and roll them in flour. For a heavier coating, the pieces may be dipped in batter or milk and egg mixture and rolled in soft bread crumbs. Preheat a heavy frying pan to a temperature of about 360° to 365°F, using approximately $^1/_2$ inch of frying fat. Turn the pieces frequently. To avoid piercing the muscle fibers, permitting the juices to escape, tongs or two spoons may be used to turn the pieces. Cook until well done.

The steps in preparation for DEEP-FAT FRYING are similar to those used for pan frying. The difference is that in deep-fat frying enough fat is used to cover the pieces to be cooked. Preheat the fat to 365°F, then carefully lower

2038606

the pieces into the fat. (The use of a deep-fat frying thermometer is recommended. Do not crowd the pieces. The chicken may be cooked until done, or it can be browned in deep-fat, and the cooking can then be completed in an oven. ALWAYS allow the deep-fat to regain heat before re-loading.

STEWING is the method used for cooking the larger, least tender types of poultry. Long, slow cooking at a simmering temperature is required to soften the tissues and make them tender. The utensil or kettle should be tightly covered to allow the steam to accumulate. The combination of the steam and the long, slow cooking tenderizes the tissues. Remember—simmer, do not boil. The cooking water is used for soups, sauces, gravies, or bread dressings.

FRICASSEEING or BRAISING is another method of cooking chicken. The chicken is first cut into serving portions. Then, it may be dredged in seasoned flour and browned, or simply browned in a small amount of fat, or not browned at all depending on the recipe. The chicken is placed in a deep utensil or kettle, covered with cold water; vegetables and/or seasonings are added according to the recipe being used. The kettle is covered tightly and the chicken is simmered until tender. The cooked chicken is removed from the stock; the chicken fat is skimmed off and blended with flour to make a roux. The stock is added to the roux to make a sauce, and then the cooked chicken is returned to the sauce and is ready to be served.

Boneless Turkey

The Navy procures boneless, frozen, string-tied raw turkey, and boneless cooked turkey. These boneless turkeys consist of light and dark meat. Instructions for preparing and slicing each type are included with the specific turkey and in the L (poultry) section of the recipe service. Boneless turkey is a tasty, timesaving item that ensures portion control and ease of preparation.

Dressing

Recipes in the L (poultry) section of the recipe service include basic bread dressing recipes and many variations which may be served with chicken or turkey.

Preparing and Cooking Giblets

The giblets (gizzard, heart, and liver) that come with the eviscerated poultry need little preparation other than ordinary washing in cold water prior to cooking. One precaution to be observed during the washing of the liver is to inspect it closely to see if the bile sack that was attached to the liver could have been accidently broken. If it has been broken, it is always easily recognized by the greenish-brown or yellow coloring that it will leave on whatever parts of the meat it touches, rendering those parts inedible. After washing in cold water, place the giblets in

TIMETABLE FOR ROASTING TURKEY L-G POULTRY No. 5

Turkey is done when meat thermometer inserted in thigh muscle reads 190° F. If no thermometer is available, move the leg by grasping the end bone; if the joint moves easily, the ligaments are tender and the meat is done.

ROASTING TURKEYS UNSTUFFED

Weight of Turkey	Oven Temperature	Minutes Per Pound	Cooking Time Hours Per Bird
8 to 10 lb	250° F	25 to 30	3 to 3½
10 to 14 lb	250° F	18 to 20	3½ to 4
14 to 18 lb	250° F	15 to 18	4 to 4½
20 to 30 lb	250° F	12 to 15	5 to 6

48.47.2

Figure 10-5.—Timetable for roasting turkey.

8607

just enough cold salted water to cover, bring to the boiling point, reduce the heat to a simmer, and cook approximately 1 hour or until the giblets are tender. Save the stock for gravy or dressing. Chop the giblets (do not grind) and use for the gravy or dressing.

FISH

Like meat and poultry, fish is an excellent protein food. Fish steaks and fillets are served in Navy general messes. Steaks are slices cut crosswise from large fish; fillets are lengthwise pieces taken from fish and free from bone. Fish is delicate in structure as well as in flavor and the flesh is tender and moist. Handle fish carefully. Recipes for preparing fish are in the H (fish) section of the recipe service.

The Navy also procures shellfish such as frozen shucked clams, frozen scallops, frozen shucked oysters, and frozen shrimp, to name a few. Recipes for preparing shell-fish are included in the H (fish) section of the recipe service.

Thawing Frozen Fish

Frozen fish, usually received on board in the form of boneless fillets, are wrapped and packaged in uniform-sized containers. Frozen fish should be thawed in the unopened package at a temperature of 36°F to 38°F. Thawing for mess use should never be accomplished by exposure to excessive heat or by soaking in warm water. However, it may be thawed at the prevailing room temperature, if cooked while still chilled.

Cooking Fish

Fish must be cooked through but not overcooked. Seafood prepared too far in advance, even though properly cooked, becomes dry and hard and loses flavor and succulence. When baking, temperatures should be in the moderate to moderately hot range (375°F). Fish is done when it flakes easily with a fork. Further cooking makes it dry and tough.

Use of Fat

Practically all fish varieties delivered to the mess, whether light-flesh or dark-flesh, require additional fat or oil while cooking. Fat aids in keeping the fish moist while it is browning, and makes it more palatable. A solid fat, such as butter or shortening may be "dotted" over fish. Melted fat or oil is brushed on. Fat meats, such as sliced bacon or thinly sliced salt pork, may be laid over fish. Fat may be supplied by pan frying or deep-fat frying. Fat (preferably butter fat or oil) may be added in the form of a sauce served with the fish.

Since there are no tough cuts of fish, as there are of meat, cooking fish in a large amount of water is only done when a soup, fish stew, or chowder-type dish is prepared. Usually, the water or stock is seasoned or flavored and is used in the finished food.

Seasoning

Simple seasoning is best for most fish. Salt and pepper are needed in moderation; monosodium glutamate is desirable for pointing up and holding flavor. Lemon juice and the milder herbs, such as parsley and chives are good seasonings. Seasonings are put on the surface of the fish or around it in a baking pan or they may be incorporated into a sauce, or a basting liquid that creates steam and helps to keep fish moist and flavorsome. When fish is cooked in liquid or sauce, season the fish lightly and also season the sauce.

GRAVIES AND SAUCES

Any gravy or sauce served as an accompaniment to a food is intended to complement or enhance that particular food. It is not to stand as something apart with no relationship to the food, nor is it to mask the food. It is important to consider the suitability of a gravy or sauce for its particular purpose.

The O (sauce) section of the recipe service contains many recipes for gravies to be served with meats and poultry, sauces to be served with fish and vegetables, and sweet sauce to be served with desserts.

Recipes for gravies and sauces often include a statement about making or using a "roux." The roux is the melted fat and starch base that is used mainly for thickening sauces, gravies, and soups. This is the key step in making a successful gravy or sauce. The roux is cooked over extremely low heat for 10 to 15 minutes. An important thing to remember is that flour alone must never be put into hot liquids for it will cook promptly into hard lumps that cannot be cooked or stirred smooth. The darker the roux, the darker and more highly seasoned the sauce in which it is used. Stock or vegetable juices are used with the dark roux. The light roux is the combination of butter and flour that is blended

8608
1038

together over extremely low heat, but is not allowed to brown. Milk is used as the liquid for cream or white sauce. The roux, in either type, must be thoroughly cooked so that no taste of starch remains. When starch is cooked in liquid, the granules burst or rupture and take up moisture. Cooking must be sufficient to burst all the starch granules or the taste of raw starch remains, and the gravy or sauce is insufficiently thickened.

Sweet sauces or dessert sauces give the delightful finishing touches that raise dessert dishes above the average, and enable the cook to be clever in offering many surprises in serving puddings, cake, fruit, and ice cream. Many dessert sauces are named for the chief flavoring ingredient, such as butterscotch, lemon, nutmeg, orange, and vanilla sauces. These sauces are made principally from corn starch, sugar, water, butter, salt, and the flavoring agent indicated by the name. Occasionally, milk and eggs are used in the preparation.

VEGETABLES

Vegetables of all types are nutritional necessities in a well-balanced diet. In addition to the contribution of important minerals and vitamins, vegetables add color, flavor, and interest to meals. All too frequently, vegetables are rejected or left uneaten when they are poorly cooked and, therefore, not pleasing in appearance or flavor. A vegetable can become unpopular simply from being overcooked, watery, or poorly seasoned. Furthermore, food values are lost or diminished by improper handling and cooking.

Vegetables are bought by the Navy in the following forms: canned, dehydrated, frozen, and fresh.

Canned Vegetables

Vegetables that are canned have been cooked in the container and need only to be brought to boiling temperature just before they are served. Never boil a canned vegetable; always avoid overheating or overcooking. Save the liquid from canned vegetables to use in soups, sauces, and gravies. See figure 10-6, guide for heating canned vegetables.

Dehydrated Vegetables

Dehydrated vegetables are increasing in popularity in Navy general messes. Their small weight and volume make them convenient to store. They are easy to prepare; all the precooking tasks associated with raw vegetables have been done for you. They are peeled, diced, sliced, or chopped, and ready to use. They ensure portion-control.

The aim in dehydrating is to remove most of the water from the food—sometimes 99 percent of it—without damaging the product. The atmospheric (hot air) method is used for vegetables. The vegetable is cut into small pieces and spread out on trays which have slats or wire bottoms. The hot air is passed over and under the trays to dry the vegetables. In-package desiccation sometimes is used to remove the last small amount of water from dehydrated foods. A small envelope containing a chemical (activated lime) is put into the final package. It absorbs water from the food during storage.

Precooked potato granules, sliced raw potatoes, raw cabbage, sliced onions, and green peppers are some of the dehydrated vegetables used by the Navy. They are reconstituted by adding a measured quantity of the vegetable to a measured volume of water. The temperature of the water will vary with the specific dehydrated vegetable being reconstituted as will the length of time required in the reconstituting process. It may vary from 15 to 30 minutes in time and the water may be either lukewarm or cool. Recipes in the Q (vegetable) section of the recipe service give more detailed instruction for reconstituting dehydrated vegetables.

Frozen Vegetables

Frozen vegetables have the appearance and flavor of fresh vegetables, and like the dehydrated vegetables discussed previously are easy to prepare; the precooking tasks have been done. Frozen vegetables have been cleaned and trimmed and are ready to use.

Quality, palatability, and sanitary aspects of frozen vegetables require that they be handled carefully. They must be kept at 0°F until ready for use. Partial thawing is detrimental to the quality, and once partially or fully thawed, they must be used immediately and not allowed to refreeze.

The guidance card, (Q-G, vegetables, No. 2) in the Q section of the recipe service prescribes the method and timing for cooking frozen vegetables. Some may be added directly to boiling water in their frozen state; others should be partially thawed. When the guidance card specifies that a vegetable, spinach for example, should be partially thawed prior to cooking, the frozen spinach is removed from the freezer and placed

Q-G. VEGETABLES No. 1 (1)

GUIDE FOR HEATING CANNED VEGETABLES

YIELD: 100 Portions (Approximately 22 Pounds)

EACH PORTION: 1 Heaping Serving Spoon (Approximately 3½ Ounces)

INGREDIENTS	WEIGHTS	MEASURES	APPROX. AM'T OF LIQUID PER CAN	METHOD
Asparagus, spears or cut up	36¼ lb.	40–No. 300 can	¾ cup	1. Pour off half the liquid; save for use in making soups, sauces, and gravies.
Beans, green or wax	25¼ lb.	4–No. 10 can	1¼ qt	2. Place vegetable and remaining liquid in steam-jacketed kettle.
Beets	26 lb.	4–No. 10 can	1 qt	3. Bring to serving temperature, approximately 10 minutes; stir gently occasionally while heating. Do not allow to boil.
Carrots	26¼ lb.	4–No. 10 can	1 qt	
Corn, whole grain	25½ lb.	4–No. 10 can	1 qt	4. Season and garnish as desired.
Okra	28 lb.	28–No. 303 can	½ cup	
Peas	26¼ lb.	4–No. 10 can	1 qt	
Spinach	30½ lb.	5–No. 10 can	1 qt	
Tomatoes	25½ lb.	4–No. 10 can	1 qt	

NOTE: 1. Prepare vegetables in small batches (determined by service rate) to prevent breaking up, discoloration, and overcooking.

2. Asparagus and spinach may be heated directly on the steam table in serving pans to prevent breaking up.

Q-G. VEGETABLES No. 1 (2)

Beans, lima	26¼ lb.	4–No. 10 can	¾ qt	1. Place entire contents of cans in steam-jacketed kettle.
Corn, cream style	24 lb.	24–No. 303 can	.....	2. Bring to serving temperature, approximately 10 minutes; stir gently occasionally while heating. Do not allow to boil.
Peas, black-eyed	24 lb.	24–No. 303 can	¼ cup	
Peas, field	24 lb.	24–No. 303 can	¼ cup	3. Season and garnish as desired.
Sauerkraut	25 lb.	4–No. 10 can	½ qt	

NOTE: 1. Prepare vegetables in small batches (determined by service rate) to prevent discolora- and overcookina.

48.47.3

Figure 10-6.—Guide for heating canned vegetables.

18610

in the chill box in its original container, until touch-test indicates that partial thawing has been accomplished.

Preparing Vegetables for Cooking

Most raw fresh vegetables have waste or portions which are not edible. When you peel, scrape, brush, trim, or cut these vegetables, it is important that you not destroy or damage edible portions and, especially, that you not lose the valuable nutritional elements which are contained, usually, close to the outer skin or peel. Select vegetables about equal in size, or cut them into pieces of equal size. Then all the pieces will be cooked uniformly in the same length of time. Plan for cooking vegetables with the peel on whenever possible, especially potatoes. If potatoes must be peeled, do it very carefully so as to make thin peelings. Much of the food value in a potato lies close to the skin. WASH ALL FRESH VEGETABLES THOROUGHLY. Use a brush to clean celery, carrots, beets, potatoes, turnips, parsnips, or any vegetable that is pulled or dug from the soil.

Tightly-grown blossoms, heads, or stem-type vegetables, such as asparagus, broccoli, cabbage, cauliflower, and brussels sprouts, will harbor worms and insects which may not be dislodged by casual washing. Soak vegetables of this type in SALTED COLD WATER (1 tablespoon salt to 1 quart of water) $^1/_2$ to 1 hour, and then rinse them. Turn cauliflower blossoms end down in the soaking water; cut cabbages in halves or quarters and remove the cores.

Wash the leaf-type vegetables such as spinach, chard, kale, and turnip greens in several changes of cold water to remove dirt and sand particles. Lift these vegetables from the water instead of draining the water off. The dirt and grit will remain in the washing pan or sink. If this water is drained or poured off, the dirt will remain on the vegetables.

After vegetables have been washed clean, keep them in a cool storage place until you are ready to prepare them for cooking.

Wilted vegetables can be freshened by placing them in ice-cold water or between layers of crushed ice. When they are freshened, the vegetables should be covered with a clean, damp cloth and placed in a cool storage room until you are ready to use them.

Keep the time between preparation and cooking as short as possible. Valuable vitamins are lost when vegetables are soaked too long or are allowed to remain at warm temperatures for several hours.

Cooking Vegetables

Vegetables may be baked or sauteed; they may be boiled or steamed; they may be served with butter or covered with an appropriate sauce; or, after being boiled or steamed, they may be creamed, mashed, or sauteed.

The basic methods of cooking vegetables are baking, steaming, and boiling. BAKING means to cook in dry heat in an oven with the addition of little or no water. Dry baking is usually limited to potatoes and squash.

STEAMING means to place the vegetables in a perforated kettle. The only water that comes in contact with the vegetables is the small quantity formed by condensation.

BOILING means to add the vegetables to boiling water and to bring the cooking water back to boiling temperature as soon as possible.

Cook only a small amount of vegetables at a time. Vegetables must be cooked in the shortest possible time, and in the least amount of water. NEVER USE BAKING SODA to preserve color. Overcooking, cooking in too much water, or using soda in the water, destroys the very elements you are trying to conserve.

In fact, undercook rather than overcook vegetables. This is especially applicable when you know the cooked vegetable is to be placed on the steam table or is to have a second heating or cooking period, such as creaming, scalloping or baking. Cover all vegetables while they are cooking, except cauliflower, turnips and those of the cabbage family, including brussels sprouts.

To test to see if the vegetable is done, press pieces between the thumb and forefinger and taste the sample. The vegetable should be tender but have a definite bite quality.

Ways to make vegetables more delicious are:

1. Cook them in soup stock (clean and free from fat).
2. Cook ham or pork bones with the vegetables, in which case do not use much of the pork fat.
3. Serve them with a garnish that has a contrasting flavor, such as minced onion, diced crisp bacon, chopped parsley or chives, a cheese sauce, chopped egg sauce, or fresh lemon.

Cooking Legumes

There are several types of dried beans that are used in the Navy mess. Legumes may be used in place of meat, as a substitute or alternate for potatoes, or as a side dish. Among the most popular are navy beans and pea beans. The cooking qualities of beans differ. Therefore,

SIGE 8611

cook only one variety, not a mixture, at one time. If large navy beans are mixed with small pea beans, the small beans will be overcooked and the large beans undercooked. See figure 10-7, guide for soaking and cooking dry beans.

FRUIT

Fruit is procured by the Navy in the fresh state, frozen, canned, dehydrated, and dried. Fresh and processed fruits may be combined to vary the flavor and texture.

Every daily menu should include some fruit. It adds color, variety, food value, and a refreshing flavor to any meal. Among the least expensive and the most nutritious of all foods, fruit has the distinction of being the most versatile.

Fruit fits into all three of your daily meals. At breakfast fruit can be served alone or in combination with cereal. It can be prepared as appetizers, salads, main dishes, soups, relishes, desserts, or snacks. It is excellent as garnishes and sometimes acts as seasoning. Fruit is an active partner in many meat dishes. Baked ham and pineapple are often teamed together, as are pork and applesauce, or turkey and cranberry sauce.

Q-G. VEGETABLES No. 3

GUIDE FOR SOAKING AND COOKING DRY VEGETABLES

YIELD: 100 Portions (Approximately 3¼ Gallons) — EACH PORTION: 1 Heaping Serving Spoon, ½ Cup (Approximately 3½ Ounces)

INGREDIENTS	WEIGHTS	MEASURES	APPROX. AMOUNT OF WATER	APPROX. COOKING TIME	METHOD
Peas, black-eyed, dry	9 lb	1½ gal	4 gal	40 min	1. Pick over beans or peas, removing any foreign matter. Wash thoroughly in cold water.
Beans, kidney, dry	9 lb	1¼ gal	4½ gal	1¼ hr	
Beans, lima, dry	9 lb	1¼ gal	7 gal	1½ hr	2. Cover with indicated amount of cold, clear water.
Beans, pinto, dry	9 lb	1½ gal	6 gal	1¼ hr	
Beans, white dry	9 lb	1¼ gal	6 gal	1¼ hr	3. Bring water to a boil; boil 2 minutes. Turn off heat. 4. Cover and let stand 1 hour.
Bacon, diced	2 lb	1¼ qt			5. Add bacon and seasonings (if desired) and bring water back to a boil.
Salt (optional)	2¼ oz	¼ cup			
Pepper (optional)	¼ oz	1 tbsp			6. Simmer for indicated time or until beans or peas are tender but not mushy. Add boiling water if beans or peas become dry.

NOTE: 1. Beans may be soaked according to Steps 1 through 4, then cooked as indicated in any particular recipe.

2. Meat stock may be substituted for water.

3. Avoid overmixing in order not to mash beans.

4. Cooking time and amount of water will depend on size, age, and variety of beans.

48.47.4

Figure 10-7.—Guide for soaking and cooking dry vegetables.

8612

Preparing Fresh Fruit

Before using fresh fruits, wash them thoroughly to remove any insect spray which may be present. If possible, pare fresh fruits immediately before using. When pared and left in contact with the air, some fresh fruits become discolored. Discoloration may be partially prevented by covering the fruit with a thin sirup of lemon juice until you are ready to use it. Peeled fruit may also be dipped in a solution of antioxidant and water to prevent discoloration. Follow the directions printed on the antioxidant containers.

APPLES may be served raw and whole for breakfast; sliced and cubed in salads or fruit cocktails; and baked, stewed, or cooked as applesauce for breakfast or dessert. Applesauce or baked apples may be used with pork roast and chops. If the skin of a raw apple is tender, leave it on.

BANANAS may be served whole for breakfast, or sliced for breakfast, desserts, salads, or fruit cocktails. Peel and slice bananas as short a time as possible before using them in order to prevent discoloration.

BERRIES should be washed and drained. Handle them carefully to avoid crushing them. Serve them raw for breakfast or dessert, raw or cooked over shortcake, and cooked in cobblers or pies.

DATES should be washed and seeded. Serve them on cereals or in cakes, cookies, or puddings.

GRAPES should be washed. Serve them raw in bunches. If they are firm, slice, seed, and serve them in salads or fruit cocktails.

GRAPEFRUIT may be served raw for breakfast or dessert and baked or broiled at low temperature with sugar for dessert. Cut them into halves crosswise and cut around the rind with a knife to loosen the pulp from each section. For salads, pare and remove each section of pulp by cutting carefully between membranes, which are very bitter.

LEMONS may be cut into halves and the juice squeezed for use in fruit drinks, pies, or puddings. For use on fish or in tea, slice or cut them lengthwise into eights.

MELONS should be cut into halves or quarters and the seeds removed. They may then be served for breakfast or as desserts. For salads or fruit cocktails, remove the pulp with a spoon and shape it into balls.

ORANGES may be served whole, cut into halves, or pared, sliced, and segmented for breakfast, desserts, salads, or fruit cocktails. Also they may be cut into halves and the juice squeezed for use in fruit drinks or desserts.

PEACHES may be served raw and whole or peeled, stoned, and sliced for breakfast or dessert. They may be cooked in shortcake, cobblers, or pies. When you peel and slice peaches, do it as near as possible to the time you plan to use them in order to prevent discoloration.

PEARS may be served raw and whole or pared, cored, and sliced for breakfast or dessert, or they may be stewed with sugar, cinnamon, cloves, or lemon.

PINEAPPLE may be served for breakfast, desserts, salads, or fruit cocktail. Pare pineapple with a long, sharp knife, beginning at the top and cutting down.

PLUMS may be served raw and whole for breakfast or desserts, or stewed with sugar for sauce or pies.

Preparing Frozen Fruit

The Navy procures frozen fruits such as berries (strawberries, boysenberries), cherries, peaches, and rhubarb. Frozen fruits are closest to the fresh counterpart in flavor and appearance. They may be thawed by placing the unopened can in the chill space 24 hours before the anticipated use. This allows the frozen fruit to thaw completely and more evenly throughout.

Preparing Dehydrated Fruits

Dehydrated fruits, such as instant applesauce, perforated apple slices, and diced apricots, are readily reconstituted by adding a proportionate volume of water to a specified weight of the particular dehydrated fruit. Like the dehydrated vegetables discussed earlier, dehydrated fruits, because of their small weight and volume, are convenient to store. Dehydrated fruits may be used for dessert in puddings, pies, and cakes, or they may be reconstituted and served at any meal.

Preparing Dried Fruit

Wash dried fruits thoroughly before using them. They may be soaked to reduce cooking time, but avoid a long soaking period because it produces a watery, tasteless fruit. Cook raisins and dates without soaking. If sugar is to be added, it should be at the end of the cooking period. If it is added at the beginning, it interferes with the absorption of water.

SALADS

Salads have an important place on the menu. They add something both nutritious and refreshing to the dinner or supper meal.

Fruit and vegetable salads are the most popular. They are also one of the best means of introducing valuable vitamins, necessary minerals, and color into the meal.

Best of all—salads can be made quickly and easily if a few simple rules are followed, and this is equally true for individual salads which often seem more appetizing and receive greater acceptance than a large dish of salad.

Salad Greens

Select you salad greens carefully. You have a wide choice of greens suitable for a salad foundation — lettuce, endive, escarole, young spinach, and cabbage. These may also be used as one of the main ingredients of the salad itself. Parsley and the inner tender leaves of curly endive are good for a garnish.

Sort, trim, wash, and crisp the greens before making the salad. Wash them carefully to free them of sand and earth particles. Drain them well. Hand cut the lettuce and cabbage into strips or pieces.

Place the prepared greens in pans. Cover them with waxpaper, if available, and then with a clean, damp cloth. Put them in a refrigerator to chill and crisp before using. They should be free of excess water. And they should be one of the very last parts of the meal to be prepared.

Vegetables for Salads

Fresh, canned, or dehydrated vegetables may be used for salads. Select the fresh vegetables with care. Wash them thoroughly. Trim and peel them if necessary and cut them into uniform sizes. Cook those which need cooking. When canned vegetables are to be used in a salad, the liquid drained from the cans should be reserved for the stock pot. The canned vegetables may be marinated in french dressing prior to being used in a salad. Dehydrated cabbage, green peppers, onions, and string beans may be reconstituted for use in salads.

The salad made from dehydrated vegetables is a welcome addition to the menu aboard ships on long endurance voyages. Whether you use fresh, canned, or dehydrated vegetables for your salad, the prepared material should be covered with waxed paper and placed in the refrigerator to be chilled. Do this before combining it with the salad greens and dressings.

Main Course Salads

Salads used for the main course for dinner or supper should be substantial and provide the food values comparable to any other main dish. These salads must include an adequate serving of high protein food, such as meat, fish, poultry, cheese, eggs, legumes (dried beans and peas), or peanuts, combined with crisp salad greens or other vegetables. Potato salad, cold or hot, may be an accompaniment to cold meats on a dinner or supper plate. Used in a salad, the starchy potato functions as it does in any other potato dish. Portions for main dish salads are comparatively large, and mayonnaise or a mayonnaise-type dressing, rather than a french dressing, is usually served with the salad.

Mixing the Salad

Mix the salad carefully JUST BEFORE SERVING. Combine the prepared, chilled ingredients in small amounts at a time. Mix or toss them lightly together. USE A LARGE FORK to distribute the ingredients and dressing.

Use of Salad Dressing

The salad dressing is an important as the salad itself. Each type of dressing can take on a new flavor by the addition of different seasonings and herbs.

As a rule, add the dressing to a fruit or raw vegetable salad the very last thing—not more than a few minutes before you are ready to serve the salad. If you are preparing salads to be set out on the salad bar, and you are placing the various types of salad dressings in separate containers so that each man may choose his own, remember to use a small size container. Any salad dressing that is left over after the meal has been served should be discarded and not kept to be used at another meal.

Serving the Salad

After care has been used to produce a crisp, refreshing and attractive salad, it must be served so that none of this attractiveness is lost. Select as cool a place as possible for assembling and serving. Bring individual salads from the refrigerator, a few at a time, so that they will lose none of their crispness.

RELISHES

Relishes are good to use in place of, or with, a salad. Raw carrots sliced lengthwise, celery,

radishes, cauliflower flowerets, strips of green pepper, olives, and pickles make excellent relishes, have high food value, and increase the attractiveness of a meal. Before serving, all raw vegetables, except leafy varieties, should be refrigerated in cold water for an hour or more to become crisp and tender.

DESSERTS

Dessert adds the finishing touch to a meal. A dessert should not be considered a sweet extra, but rather should be a part of the meal which is as important as the main course.

Rules for good meal planning demand that all foods in the meal blend together with pleasing harmony and contrasts of color, texture, temperature, shape, and flavor. All of these points must be considered when you plan the dessert. Any dessert should harmonize with the food which preceded it. With a light meal, the dessert may be a hearty one, while with a hearty meal a light dessert is in order. With a meal which has been rich and highly seasoned, a simple mild-flavored dessert is best. In this way, the dessert balances the meal.

The flavor of the dessert should blend with the other courses. To repeat much of the same flavor in a meal is monotonous. Too many sweet-tasting foods with no tart food or too many tart foods without some sweet-tasting food is not satisfying. Therefore, a tart fruit dessert seems the perfect finishing touch for a roast pork dinner, and a raisin rice pudding is a good dessert after fish served with lemon.

COFFEE

Coffee is delicate and perishable. Ground coffee loses its flavor and aroma rapidly if it is exposed to the air. Coffee deliveries are made in airtight containers, so see that these containers are kept tightly sealed.

You won't have any trouble making excellent coffee if you follow a few simple rules. Use the recipes given in the B (beverage) section of the Navy-Marine Corps Recipe Service. Always measure both the coffee and the water. Use fresh coffee at all times, and keep the coffee covered while it is brewing. Never allow coffee to remain in contact with boiling water, as the flavor and aroma will boil off. Remove the grounds as soon as the coffee is made. Seepage from the grounds will ruin the flavor of the best coffee.

Most important of all, keep the COFFEE MAKING EQUIPMENT absolutely clean. Wash the urn with clear, hot water immediately after you have used it, and at the end of the day with hot water and urn powder. Rinse thoroughly with clear water. Never use soap or soap powder. When the equipment is not in use, leave 1 or 2 gallons of clear water in the urn. Drain it before making fresh coffee.

Remove the urn faucet once a day and scrub it with hot water, baking soda, and a brush. Use a tablespoon of baking soda for each quart of water. BE SURE TO RINSE THOROUGHLY.

Clean the glass gages at least twice a week with a brush, hot water, and baking soda.

Rinse the urn bag in clear, cold water after each use. When not in use, keep the bag in cold water. Renew the cloth bag frequently.

TEA

Normally, two forms of tea are used; bulk tea and teabags. However, instant, powdered tea also has special uses in the military services.

The quality of brewed tea depends upon how fast the boiling water extracts flavor and color from the tea leaves; it is the tannin present in the leaves that gives tea a bitter taste. Improper temperatures, times of brewing, and holding for service will bring out this bitterness and the pungency characteristics of extracted tannin.

The proper quantities of both water and tea should be measured carefully. Never guess at the amounts. A rule of thumb ration to remember is $^3/_4$ to $1^1/_2$ ounces of tea to 1 gallon of fresh boiling water for hot tea. Eight ounces of tea is a sufficient amount for $6^1/_2$ gallons of water. This amount of tea is sufficient for 100 eight ounce servings of hot tea. Some important points to remember when preparing hot tea follow:

1. If loose tea, not enclosed in a cloth bag, is placed in the urn or kettle, strain tea after it has steeped for 5 minutes.
2. Tea should be made just before serving.
3. Tea should never be boiled as this imparts a bitter flavor.
4. Schedule preparation of tea so that not more than 15 minutes will elapse between its preparation and service; hold finished tea at temperatures 175°F to 185°F for service.

The following are some of the important points to remember when preparing iced tea:

1. Do not add cold water to the concentrate; this may produce a cloudy tea infusion.
2. The tea may be presweetened by dissolving 2 pounds 10 ounces ($1^1/_2$ quarts) of sugar in the hot concentrate before diluting with cold water.

8615

3. If desired, cut $3\frac{1}{4}$ pounds of lemons (13 lemons) into eights to serve with the tea.

OTHER DRINKS

The B (beverage) section of the recipe service contains many recipes for various fruit drinks and milk drinks that may be prepared and served with either dinner or supper. When preparing fruit drinks such as lemonade or grapeade, it is important to remember to make the drink early enough to allow time for thorough chilling in the refrigerator. Ice should never be added to these beverages for chilling.

SANDWICHES

Sandwiches make satisfying meals and are especially convenient for emergency use. This is true under battle feeding conditions when groups of men are isolated from regular mess facilities, or under similar emergency circumstances. When sandwiches are prepared, it must be remembered that they will probably be the primary item of that particular mean and should be substantial. Where possible, sandwiches should be served with a beverage, fruit or fruit juice, and raw vegetables to be eaten from the hand. There is no limit to the interesting and tasty food combinations that can be used for filling sandwiches. Many good recipes are listed in your Navy-Marine Corps Recipe Service.

Preparing Sandwiches

Sandwiches may be made with any kind of bread. Varying the bread helps to avoid monotony. The kind of bread used should be appropriate for the type and flavor of the filling to be used; there is no set rule for such combinations, for the choice is determined by individual taste. Sandwiches may be served hot or cold.

Use slightly firm bread when making sandwiches because it is more easily handled than freshly baked bread. Bread requires special handling to deter further staling. To prevent moisture loss or absorption, observe the tips listed below on wrapping and storing bread and rolls.

1. Retain in a moistureproof wrapper.
2. Do not store bread in chill spaces; if properly wrapped, bread stays fresher at moderate temperatures (ideally 75° to 95°F). Immediate freezing of cooled, freshly baked bread will prevent staling.
3. Maintain a dry, clean storage spot for the bread and rolls; separate from other stores to prevent absorption of odors and flavors.

The primary rule in sandwich making is MAKE TO ORDER. Advance preparation hastens food spoilage and possible infection. The timing of sandwich making is extremely important. Not more than 3 hours, cumulative time, from preparation to consumption, should elapse without refrigeration.

Handle the bread and fillings as little as possible, avoiding the use of your hands in direct contact with foods if tools or equipment can do the job efficiently. Make prepared fillings only in such quantities as will be used during on serving period. Keep filled sandwiches at a temperature of 40°F or lower if possible.

Avoid leftovers. Do not use any foods for sandwich fillings, including leftover meat and eggs, that have been held at 40°F or over for more than a few minutes. The bacteria grow more rapidly in some foods than in others. The use of pickle relish or slightly soured mayonnaise in sandwiches is of no practical value in the control of pathogens or toxins.

Fillings should not be exposed to room temperature for long periods of time, since food poisoning bacteria grow rapidly in many sandwich fillings and even in the bread itself when it is moistened by mayonnaise or salad dressing, and, especially, those fillings containing eggs, moist lettuce, tomatoes, or similar foods.

Immediately following preparation, wrap each sandwich separately, if possible, and refrigerate. Never use a dampened cloth or towel to keep bread or sandwiches moist. Avoid stacking sandwiches in large numbers or placing them in cardboard boxes. These methods of care actually insulate the food and prevent it from reaching the desired cool temperature as quickly as it should.

Sanitary Precautions

Always prepare sandwiches under conditions where the least contamination possible can occur. Such conditions are affected by installations, equipment, quality of ingredients, and the health and cleanliness of workers. Strict observance of the rules and regulations promulgated by the Medical Department is a must, and such sanitation standards will ensure consumer confidence.

The following rules and regulations should be observed in sandwich production:

1. Keep sandwich counter and equipment clean and sanitary by thorough daily care.

2. Requisition and prepare refrigerated foods in such quantities as will guarantee top-quality sandwiches, a rapid turnover, and reduce spoilage. Avoid leftovers.

3. To keep mold and undesirable odors to a minimum, clean the chill boxes and accessories regularly.

4. Handle bread and fillings as little as possible during all production processes, avoiding the use of hands in direct contact with foods if tools or equipment can do the job efficiently.

CEREALS

Cereals are foods made from grains of wheat, oats, corn, rice, rye, and barley. Cereals are often referred to as breakfast foods, but are not limited to the breakfast meal. Cereals can be used in many types of recipes.

Cereals are usually classed as carbohydrates and thus are known as energy foods. Some cereals have a great amount of protein and are body-building foods.

Cereals are divided into two main classifications—those which are TO-BE-COOKED and those which are READY-TO-EAT.

The to-be-cooked cereals have two classifications: (1) those which are prepared by QUICK-COOKING; and (2) those that require a longer cooking period (sometimes called REGULAR or OLD-FASHIONED).

Quick-cooking cereals have been manufactured to cook completely in a few minutes. In these cereals the pieces of grain are cut finer and rolled thinner than those in the longer-cooking class.

Longer-cooking, or old-fashioned, cereals must be cooked for a longer period of time so that the starch is completely changed and made easy to digest.

Cooked cereal should be free from lumps; cooked to the proper consistency; not too thick nor too thin; and well flavored. Cooked cereals taste best when served piping hot. The cooking develops the flavor and changes the cereal starch, making it soft and more easily digestible. Since cereal grains contain a large proportion of starch, the grains increase in bulk and become thicker while being cooked. The starch in cereal cooks quickly, and long, slow cooking is not necessary. So that cooked cereal will retain its full flavor and not become too thick, it is best to cook it shortly before serving.

Flaked cereals such as rolled oats and whole wheat cereal are cooked by sprinkling them into boiling, salted water. Granular cereals such as farina and cornmeal are made into a paste, using cold water, and then added to boiling, salted water. The water should continue to boil while the cereal is being added. Vigorous stirring or beating of cereal while it cooks tends to make it sticky and gummy.

EGGS

Eggs are valuable foods which contain protein for building and repairing muscles, plus minerals and vitamins for good health. Eggs are easily digested, and, if properly cared for and prepared, are delicate in flavor.

There are literally hundreds of ways in which eggs can be used in food preparation. Below are special uses with other foods:

1. Thicken custards, puddings, and sauces.
2. Leaven cakes and cookies.
3. Add color, richness, and flavor to any dish in which they are used.
4. Help provide a coating on breaded meats, fish, or croquettes.
5. Serve as colorful, good-tasting garnish for salads, soups, or cold meat platters.
6. Bind ingredients together as in meat or fish loaves, croquettes, and patties.
7. Emulsify (help keep the right consistency of) salad dressings.

The Navy procures fresh shell eggs, frozen whole table-type eggs, frozen egg whites, frozen egg yolks, and dried whole eggs.

When several fresh eggs are to be used, break each one separately into a small dish. Thus any egg which may have a strong odor or poor appearance can be discarded without spoiling the others.

Frozen whole table-type eggs are to be used for scrambled eggs and omelets. The bakery-type, frozen egg yolks, and frozen egg whites are to be used only in baking.

Whole dried eggs may be used in cooking and baking or they may be scrambled. Instructions are included on the recipe cards for using whole dried eggs in baking.

When you are using whole dried eggs as scrambled eggs, prepare no more than 25 portions at one time and prepare them less than 10 minutes before serving; they toughen if allowed to stand. Reconstitute whole dried eggs carefully with cool water using the instructions included with the product. Once reconstituted, the eggs must be used within 1 hour. Diced cooked bacon, ham, sausage, luncheon meat, or cheese may be added to the eggs. Whole dried eggs, reconstituted with water, are used in the same way as fresh eggs, and should

8617

be treated with the same care as fresh eggs removed from the shell. Dried eggs should be sifted before measuring or weighing for reconstituting. If a sifter is not available, the powder should be stirred with a fork or a wire whip to make it light and fluffy.

Dried whole eggs will absorb moisture if they are exposed to air; consequently, they should be stored in a cool, dry place in tightly covered containers. If they are properly stored at refrigerator temperature, whole dried eggs will be satisfactory for at least a year. Whole dried eggs, left uncovered near strong-flavored foods such as onions, lemons, or cheese, will absorb odors and flavors as readily as do fresh eggs.

Eggs which are stored at room temperature or allowed to remain at room temperature for a number of hours, rapidly deteriorate in quality.

8618

CHAPTER 11

BAKING

Although procurement of bread, pies, cakes, and simple pastries is authorized, you will be expected to know how to make them. This is particularly true on small ships and at smaller shore stations, where conditions will permit serving hot breads and baked dessert items.

To produce high quality bakery products, you should learn certain general facts about each type of product. Eash has a basic recipe which may be varied to some extent, but which must remain essentially the same to produce a satisfactory result. You should understand this recipe and the interaction of its ingredients which causes the dough or batter to rise and produces other effects necessary to the final product.

The different kinds of dough and batter are handled and panned in specific ways to produce best results, and for each type there are instructions about baking time and temperature. Also, certain precautions must be observed to protect the products from spoilage.

BAKESHOP EQUIPMENT

Any discussion of baking is incomplete without a discussion of the equipment used and its operation. The electric mixer is discussed in chapter 5. On smaller ships, you will use a machine similar to this to mix bread and cakes, as well as other foods. On larger ships, where there is space for a separate bakeshop, you will use a BREAD-DOUGH MIXER. Bread-dough mixers should not be confused with food mixing machines.

Bread-Dough Mixer

If you are to use the dough mixer wisely, without danger of overloading, it is important that you know the capacity of the particular machine in your shop. This capacity is expressed in barrels. When dough mixers were first made, flour was packed in barrels, and the size of the mixers was designated by the number of barrels of flour they could mix. Since 1 barrel of flour weighed 196 pounds, a 1 barrel machine was designed to mix a dough containing 196 pounds of flour (a 360 pound dough).

Where speed is concerned, there are two types of dough mixers, no matter what their capacity. The low speed mixer which is used aboard ship operates at 26 rpm. The high speed mixer used for shore activities has a combination of 2 speeds and can be operated at low speed, 33 rpm, or high speed, 65 rpm. The baker must determine the exact time needed to mix a dough properly in the particular mixer in his shop. It takes longer to mix the dough in a mixer which operates at a low speed than in one that operates at a higher speed.

Also, the amount of friction heat developed by the high speed mixer will be greater than that developed by the low speed mixer. Since this amount of heat will affect the development of the dough, it will be necessary for you to determine the exact temperature rise from mixing on a particular machine. The temperature of the dough can be maintained at the desired level by controlling the temperature of the water used in mixing the ingredients.

Safety Precautions.—There are certain safety precautions for operating mixing machines. First, of course, the machine should always be properly cleaned to protect the product. For your own protection, never reach inside the machine when it is running; don't get water on any of the electrical parts or the motor; and always be sure that the power is switched OFF before cleaning.

Care and Cleaning.—The bread mixer should be cleaned after each use, unless doughs are being mixed one after the other. In this case, the machine should be cleaned immediately after

0508 8619

the last dough is out. You should take care to remove all particles of dough and ingredients from all parts of the machine, particularly the places that are not visible, such as the underside of the cover.

Like any other machine, the dough mixer requires grease or oil, and sometimes both. The mixing machine should be properly lubricated to do the job. However, it is the responsibility of the baker to request lubrication service as often as necessary to keep the mixer in good operating condition. The mixer is a rugged piece of machinery and is not likely to break down if it is kept lubricated and is not overloaded.

Dough Trough

A dough trough is the container in which dough is placed during the fermentation period. It is an oblong box-like trough of steel construction (see fig. 11-1), equipped with 4 casters to permit easy movement in the bake shop area.

Dough troughs are of various lengths, and are designed to hold approximately 90 pounds of dough to a foot of length or 50 pounds of flour to a foot. If the trough is too long for the amount of dough to be fermented properly, dam boards may be inserted so that the correct amount of space is available.

It is important that the dough trough be thoroughly cleaned after each use. After cleaning, rub the inside with oil to prevent rusting.

Figure 11-1.—Dough trough. 48.50

Dough Proofers

Dough proofers or fermentation rooms are used for conditioning dough and cooling baked bread. The air temperature and air moisture (humidity) in a dough proofer are kept at preset levels by automatic controls. Dough proofers are thermally insulated enclosures and vary in size from a small box with shelving to a room with space for many portable bread racks. Heating of dough proofers is done by steam coils or electric heating elements inside the enclosure, or by self-contained air conditioning units connected with the proofer by air ducts. For shipboard use, steam heated dough proofers (fig. 11-2) are furnished in various sizes; the number and size of the proofers depend on the capacity of the bake ovens installed on board ship.

Figure 11-2.—Dough proofer. 48.51

Operation.—Regardless of the size, the operation of dough proofers is basically similar. Air within a proofer should be kept at a preset temperature and moisture level. Dough proofers require not less than 1 hour to attain proper atmosphere; the unit should be started well in advance of anticipated use.

For proofing Navy bread dough, the time and temperature in the proofer should be that specified on the recipe card being used. Turn the steam valve on full and open the pet cock to provide the necessary amount of steam for humidity. Adjust the steam inlet valve to obtain the desired temperature. When the temperature and humidity are correct, place the pans of dough within the proofer and close the door.

Watch the time closely, and test the dough periodically by pressing fingers into it. If the depression is filled by rising dough, fermentation is progressing properly. To reduce fermentation, cover the bread pans with cloths and reduce the proofer temperature. At no time should there be more than 35 pounds of steam pressure allowed to pass through the steam coils of the proofer. Drain the condensation from the drip pan at regular intervals by opening the pet cock.

Care and Cleaning.—Proofers should be maintained in a safe, sanitary, dustfree, rustfree, nonleaking, and economical operating condition. The enclosures and accessories should be kept free of flies, ants, cockroaches, mice, and rats.

At the end of each day, proofers should be swept clean; shelves and racks removed and scrubbed with hot soapy water and rinsed with 180°F water. When practicable the inside of the proofer should be scrubbed daily with hot soapy water, rinsed with 180°F water, and dried immediately.

Bake Ovens

Bake ovens (fig. 11-3) are furnished the Navy in four types: types 4, 6, 12, and 18. Types 4 and 6 are the older type ovens having 4 and 6 compartments, respectively. In those ovens the heating elements are located at the bottom of each compartment and at the top of the upper compartment. Each heating element is controlled by three-heat switches. Each baking compartment is equipped with a temperature indicator. The bake oven is also provided with means to prevent overheating by limiting the maximum temperature attainable in any compartment to 500° or 550°F under any operating condition.

The type 12 (2 compartments) and type 18 (3 compartments) are the newer design of bake ovens. These ovens have the same available oven space as the type 4 and type 6, respectively. Each oven compartment of the newer type is heat insulated from the others and is controlled separately by an adjustable thermostatic switch. Top and bottom heating elements in each section are controlled separately by three-heat switches.

Operation.—When ready for use, the oven should be preheated to the desired temperature with all switches on "high" position, then turned to "low" or "medium" as desired. Make every effort to avoid excessive opening of doors. Steam should not escape around the doors. Avoid direct air currents on ovens. Keep dampers as nearly closed as possible.

Load the decks evenly, distributing products uniformly over the deck area not closer than 3 inches to the door. Load the pans in rows from rear to front of the oven along the right wall. Follow this procedure until the oven is full. Start unloading with first row on the right; this procedure gives even baking for each pan.

Care and Cleaning.—Keep the inside of the oven and decks scraped clean to avoid spotty heating, particularly around doors and edges. If dirt accumulates, the doors will not close tightly, and poor baking will result.

Cool the compartments by opening the vents, using the control rod at the front of the oven. DO NOT throw water in the oven to cool the oven decks or to wash them. When you use a wet rag to swab or clean the decks, wring it out thoroughly before using.

Dough Thermometer

A dough thermometer is an essential instrument in any shop that is producing bread. It is

48.52

Figure 11-3.—Bake ovens.

8621

used for determining the temperature of the room and of the flour and water used in the bread dough and, after the dough is mixed, the temperature of the dough. In order for the yeast to function uniformly and at a proper speed, the dough must be at the correct temperature. The temperature of the ingredients added to the dough and that of the room in which it is mixed, as well as the heat generated in mixing, will affect the final temperature. Without a thermometer, you will not be able to determine any of these temperatures accurately. The highest reading of the dough thermometer is 120°F. Keep it out of extremely hot water.

Bread Racks

Bread racks should be used for cooling or for proofing bread. The rack may be filled with pans of molded (shaped) loaves of bread and put in the proof box for the time required for proofing. In the cooling process, after the bread has been baked, the bread should be placed on the trays from the top down and about 1 inch apart.

Bread racks should be washed at frequent intervals to prevent dirt, crumbs, and foreign matter from falling on the bread.

Work Bench

The wooden work bench is used primarily for the makeup of handmade baked products. It should be permanently secured to avoid its being moved to a position where it may cause an accident. It should be checked for wood splinters which could get into the bread or injure the baker. It should never be used like a meat block, but instead should be protected from nicks and cracks, and scrubbed after each day's use.

Scales

Scales take the guess work out of measuring. They save time and are the most accurate way of measuring ingredients. Scales are usually on the ship's allowance, and it may be that only one pair is available on the ship. This means that great care must be exercised in handling them. They should be checked often to make sure that they are working properly. Scales are of two general types: the spring type and the balance type. These scales weigh to the nearest $^1/_4$ oz.

Pans

Pans for bread, rolls, cake, and pie constitute a major investment in every bakery operation. A knowledge of the care and maintenance of these pans is essential if they are to remain usable for the maximum time.

Pans are made of tinplate (the most commonly used), aluminum, and aluminized steel.

Maintenance.—All baking pans should be kept clean. Dirty pans affect the baking quality, are unsanitary, and often will impart objectionable odors or taste to the finished product. Pans may be washed by three methods: hand washing, tank washing, or with a pan washing machine. For each washing method, it is important that the proper pan cleaning material be selected. The cleaner must be powerful enough to remove the carbon and dirt and yet not harm the surface coating of the pan. The proper solution as recommended by the compound cleaner manufacturer must be followed in each case. The wrong solution can result in the complete ruin of the pan. After the pans are cleaned, they should be immediately and thoroughly dried by allowing them to air dry. Pie pans may be dried by separately placing them in a 380°F oven for about 15 minutes.

Storage and Handling.—Pans should always be stocked neatly, upon a clean pan truck or skid, to a safe height to allow the average person to remove the top pans easily. Pans should be stacked inverted to prevent contamination and to facilitate handling. If the pans are to be stored for a considerable time, they should be thoroughly cleaned to remove the pan grease and then covered with a fitted canvas duck or wrapped with kraft paper. The first day of storage should be marked on a obvious part of the wrapping surface. The purpose of dating the covering is so that the baker can schedule inspections of the stored pans and so that the covering will be replaced frequently enough to avoid dust and contamination accumulating on the covering and pans.

When pans are stored they should not be exposed to outside weather because corrosion may occur. The pan temperature also can be lowered enough to cause condensation to form during proofing. Low pan temperature also affects the quality of the proof, and the moisture from condensation can cause serious sticking problems at the pan dumping area.

188622

Do not bang and slam the pans. This distorts them and causes excessive strain on the strappings, leading to premature deterioration. Dented and bent pans cause poorly baked products, lead to malformed baked goods, and frequently are the cause of poor release qualities.

Bread Pans

Bread pans are made of steel and coated with tin. New pans should be treated before they are used so that the tin will be harder and less porous. This will help keep the bread from sticking. The process of treating the new pans is known as BLUEING OR BURNING OUT pans.

To burn out pans, follow these steps:

1. Thoroughly clean the pans.
2. Place pans in the oven and raise the temperature to 410°F.
3. Keep temperature of 410°F until the pan takes on a blue color.
4. Turn off oven and lower the temperature to below 275°F.
5. Remove the pans and grease them lightly while they are still warm.
6. Place pans in the oven and keep them warm for 1 hour.
7. Remove the pans from the oven; grease them prior to use when they are cold.

NOTE that it is very important for you to control the temperature of the oven to prevent melting the tin coating on the pans. Remember also that sliding pans on the hot oven deck may cause the tin coating to rub off the bottom.

Bread pans which are being used daily should be lightly greased to prevent sticking. Normally, sufficient fat is used in the dough so that it is not necessary to grease the bread pans after each use. The amount of grease used in a bread pan should be just enough to prevent the loaf from sticking to the pan.

All pans should be kept clean and dry to avoid rusting.

Pie Pans

Pie pans are round pans, the sizes being designated by the width (diameter) of the pan in inches. There are several good rules to observe in order to keep pie pans in good condition and to ensure a longer life.

1. Clean pans after use, and dry thoroughly (in the oven not above 380°F).
2. When you cut pies, avoid cutting or scratching the pan.

Muffin Tins

A unit in a muffin tin is approximately $1\frac{1}{2}$ inches in diameter, but the units vary in depth. The average pan has 12 units. The importance of keeping these pans well greased and clean cannot be overemphasized. If the pans are dirty, it will affect the finished product.

Avoid letting rancid grease accumulate in the crevices and corners of these pans. A good procedure to follow in caring for the pans is as follows:

1. Grease pans prior to use. Use a plastic grease.
2. Flour pans after greasing to avoid having cakes or muffins stick to the pans. Paper liners are now available for muffin tins. Your supply officer can order them for you.
3. Clean and dry pans after use. Do not grease.

BAKING INGREDIENTS

Many of the characteristics of bread are brought about because certain changes take place in the dough before it is baked. A knowledge of ingredients must include an understanding of the effects of time and the conditions to which the dough is subjected. As you read this discussion, refer to figures 11-4 and 11-5, which show the Navy-Marine Corps Recipe Service recipes for white bread, regular and short time, respectively.

The flavor of bread results partly from the blending of the ingredients in the dough and partly from changes that take place before and dough is baked. The color of the crust results from the sugar caramelizing in the presence of heat. The volume of the loaf is a result of the combined action of flour and yeast in the presence of water.

The basic ingredients of bread are flour, water, salt, and yeast. Additional ingredients will add to the normal characteristics of the bread, such as improving the flavor, color and volume, and contributing to the food value. Common among such enriching ingredients are sugar, shortening, and milk (milk solids).

Flour

There are four grains that are commonly milled into flour. These are wheat, corn, barley, and rye. Of these, wheat is the only one that contains properties that make it possible to produce a raised bread. The wheat contains protein which when combined with water forms

8823

WHITE BREAD — C. BREADS No. 13 (1)

YIELD: 30 Loaves (47½ Pounds of Bread) — DAILY RATION: 6 Slices

INGREDIENTS	WEIGHTS	MEASURES	% ON FLOUR BASIS	METHOD
Yeast, active, dry	5 oz	1 cup	1.11	1. Sprinkle yeast on top of water. Let stand 5 minutes, then stir. Add sugar, stir until dissolved. Let stand 10 minutes longer, then stir again.
Water, warm (110° F)	.....	1½ pt	.....	
Sugar	2 oz	4½ tbsp	.....	
Water (68° F) variable	.....	2⅛ gal (variable)	65.49 (Total)	2. Place water in mixer bowl. Add salt, sugar, and milk; mix on low speed to break up any lumps.
Salt	11 oz	1¼ cups	2.43	
Sugar	1 lb 13 oz	1 qt	6.86 (Total)	
Milk, nonfat, dry	1¾ lb	5¾ cups	6.19	
Flour, hard wheat, sifted	28¼ lb	28¼ qt	100.00	3. Add flour, yeast suspension, and shortening; mix until dough is smooth and elastic, (approximately 15 minutes, on medium speed).
Shortening, soft	1 lb 6 oz	3¼ cups	4.87	4. FERMENT: Set in warm place (78° to 80° F), free from drafts, until double in bulk (approximately 2 hours). 5. PUNCH: Let stand 30 to 45 minutes. 6. MAKE UP: Scale loaves at 28 oz, round up and let rest 10 minutes. Mold and place one loaf into each bread pan (11 by 5¼ inches). 7. PROOF: Place in a warm place until double in bulk, approximately 1¼ hours. 8. BAKE: 425° F approximately 35 to 40 minutes.

C. BREADS No. 13 (2)

NOTE: 1. A ½-inch bread slicer will yield 20 slices (plus 2 end slices); a 7/16-inch slicer will yield 23 slices (plus 2 end slices).

2. 10 oz of compressed yeast may be substituted for active dry yeast.

3. Temper water to yield a dough temperature of 80° F.

VARIATIONS

1. CINNAMON BREAD: In Step 6, after dough has been divided and scaled, roll each piece into a rectangular sheet. Brush with melted butter, sprinkle generously with Cinnamon Sugar Mix (Recipe Card I-24). Brush bottom edge of each piece of rolled dough with water then roll as for jelly roll. Seal on bottom and place one roll in each greased bread pan (11 by 5¼ inches). Sprinkle top of each roll with Cinnamon Sugar Mix. Proceed with Steps 7 and 8.

2. CRACKED WHEAT BREAD: Use 3 lb wheat base (approximately 10%) and 25 lb sifted hard wheat flour in Step 3.

3. RAISIN BREAD: Add 4 lb of raisins during the last 2 minutes of mixing in Step 3.

BAYONNE BREAD C. BREADS No. 15 (1)

(short-time, white bread formula)

(NAVSUPRANDFAC, Bayonne, N. J.)

YIELD: 30 Loaves (47½ Pounds of Bread) DAILY RATION: 6 Slices

INGREDIENTS	WEIGHTS	MEASURES	% ON FLOUR BASIS	METHOD
Yeast, active, dry	8½ oz	1⅔ cups	1.82	1. Sprinkle yeast on top of water. Let stand 5 minutes, then stir. Add sugar, stir until dissolved. Let stand 10 minutes longer, then stir again.
Water, warm (110° F)	.....	5 cups	.....	
Sugar	3 oz	6¾ tbsp	.....	
Water (65° F) variable	.....	2 gal (variable)	63.25 (Total)	2. Place water in mixer bowl. Add milk, sugar, and dough conditioner. Mix on low speed to break up any lumps.
Milk, nonfat, dry	1½ lb	4¾ cups	5.13	
Sugar	14 oz	2 cups	3.63 (Total)	
Dough conditioner (optional)	2½ oz	4½ tbsp	.53	
Flour, hard wheat, sifted	22 lb	5½ gal	100.00 (Total)	3. Add flour and start mixer on low speed; add shortening and yeast suspension. Mix until flour is thoroughly moistened.
Shortening, soft	1 lb 6 oz	3⅛ cups	4.70	4. Mix on medium speed 10 minutes.
				5. Let rise in mixer bowl 20 minutes.
Flour, hard wheat, sifted	7¼ lb	7¼ qt	.....	6. Mix and sift flour, salt, and cornstarch; add and mix on medium speed 10 minutes or until dough is smooth and elastic.
Salt	8½ oz	1 cup	1.82	
Cornstarch	5 oz	1 cup	1.07	
				7. FERMENT: 30 minutes at a dough temperature of 88° to 90° F.
				8. MAKE UP: Scale 28 oz of dough into each bread pan (11 by 5¼ inches).
				9. PROOF: 25 to 30 minutes at 90° F or until double in bulk.
				10. BAKE: Preheat oven to 450° F. Bake 5 minutes. Reduce temperature to 375° F. Bake 25 to 30 minutes.

C. BREADS No. 15 (2)

NOTE: 1. A ½-inch bread slicer will yield 20 slices (plus 2 end slices); a ⅞-inch slicer will yield 23 slices.

2. 1 lb 1 oz of compressed yeast may be substituted for active dry yeast.

3. Water temperature and fermentation are based on a final dough temperature of 90° F.

4. Loaf units do not necessarily require molding. Roll scaled dough to pan size and place directly in pan.

VARIATIONS

1. RAISIN AND MOLASSES BREAD: Use 3 oz brown sugar in place of sugar in Step 1. Use 14 oz brown sugar in place of sugar and add 4 oz (1 cup) cinnamon in Step 2. In Step 6, omit corn starch and add 1 qt molasses. During the last 2 minutes of mixing in Step 6, add 4 lb raisins which have been "puffed" (See Recipe Card C–12). In Step 7, ferment for 1 hour. Proceed with Steps 8 and 9. Bake: at 350° F for 35 minutes.

2. WHEAT-TYPE BREAD: In Step 6, use 3¼ lb wheat base and 4 lb (4 qt) sifted hard wheat flour. Proceed with Steps 7, 8, 9, and 10.

Figure 11-5.—Recipe for making bayonne bread. 48.47.6

088625

the elastic substance GLUTEN, which gives the dough expansion qualities.

Wheat flour is divided into hard and soft varieties, depending on the type of wheat from which it is milled. Hard flour contains more protein and is used for making yeast bread and rolls, while soft flour is used for cakes, pastries, and, when blended with hard wheat flour, for quick breads. A hard wheat flour containing a good quality gluten is called a "strong flour." A low protein of soft wheat flour forms less of the gluten and a less tough type so that sufficient structural material will be provided for cakes and similar products, without causing them to be too tough.

Flour contains various food elements besides the protein. These are fat, carbohydrates, water, minerals, and vitamins, the content varying with the type, grade, and storage period of the flour. It is little wonder that bread made from such ingredients is called "the staff of life".

Although the FAT content of flour is very low, this fat will become rancid if flour is stored for long periods under unfavorable conditions.

CARBOHYDRATES in flour are usually in the form of STARCH, which absorbs water and helps give bulk to the dough. Flour especially made for cakes and pastries is rich in carbohydrates.

MINERALS are contained in the bran coat and the germ of wheat, and most of the minerals are lost when wheat is made into white flour. These minerals have been returned to enriched flour.

DIASTASE and PROTEASE are the most important enzymes found in flour. An enzyme is a very minute substance produced by a living plant, which, by its mere presence, brings about certain changes in the composition of a material. Diastase converts starch to sugar, and the yeast acts upon the sugar to produce carbon dioxide and other fermentation products. Protease softens the gluten, and when this enzyme is lacking, the dough will not be elastic.

All flour is aged chemically and no additional aging or blending is required.

Water

Water is one of the basic ingredients of bread. In many bakery products, including bread, the amount of water used is second only to the amount of flour. Water contains minerals. The amount and kind vary in different parts of the world. These variations affect the properties of dough and the finished bread.

Functions in Baking.—Water is necessary to form gluten from the protein of flour; this gives dough its elastic and gas retaining properties. Gluten absorbs twice its own weight of water. The amount of water used determines the consistency of the dough temperature after mixing. Water dissolves salt and sugar and aids in distributing these materials uniformly through the dough. Water makes its possible for the enzymes to act on flour, and for the yeast to cause fermentation.

Leavening Agents

Leavening agents are gases that cause dough to rise. They are produced by chemical action or introduced by the mixing process, which forces air into the dough. The common types of leavening agents are steam, air, and carbon dioxide gas.

Air is introduced into dough by blending (creaming) fat and sugar together, by sifting flour, or by folding in beaten egg whites which already contain air. Steam is used to leaven popovers and cream puffs. Carbon dioxide gas is created by using yeast, baking powder, or soda in the dough.

YEAST is a microscopic, one-celled plant which when conditions are favorable, will multiply by budding or by the division of a cell into two cells. In this process of reproduction, the yeast plant uses available food (sugars) to produce carbon dioxide gas and alcohol. This is known as fermentation.

Two kinds of yeast common in the Navy are COMPRESSED YEAST and ACTIVE DRY YEAST. By weight, active dry yeast is considered to be twice as strong as compressed yeast.

Compressed yeast should be broken up and suspended in a part of the water ingredient. The amount of water used will have an influence on the degree and ease with which the yeast can be distributed through the dough. Never use less than 1 quart of water to a pound of compressed yeast. For best results, allow yeast to remain in water for 5 to 10 minutes before adding it to the dough.

The water should be approximately 80°F. If the yeast is cold, warmer water (never over 95°F) will be required to activate it. Before adding the yeast water to the dough, distribute the salt of the formula thoroughly through the other ingredients.

Active dry yeast should be suspended in about four times its weight of water at 105°F to 110°F for 5 to 10 minutes before use. Colder water results in slower fermentation, while water which is much warmer may harm the yeast.

Complete distribution of the yeast cells throughout the dough is very important whether the yeast used is compressed or active dry. The total cells in the finished loaf of bread are limited to the total number of active yeast cells in the piece of dough at the time the loaf was being pan proofed.

BAKING POWDER is a leavening agent which contains carefully measured amounts of baking soda and a material which forms an acid when it is mixed with water. To keep these active ingredients separated, and prevent the moisture in the air from causing them to act with each other, they are mixed with a large amount of starch. It is required that they produce not less than 12 percent carbon dioxide. There are several types of baking powder, the type determined by the chemical which is used to form the acid. The Navy uses a combination type baking powder, S.A.S., which contains 2 acid ingredients: sodium aluminum sulphate and orthophosphate. This type of baking powder is moderately fast acting; one constituent acts in the batter, while the other does not act until it is heated in the oven.

Carbon dioxide may also be produced by combining baking soda with sour milk or molasses. It is difficult, however, to determine beforehand the amount of gas that these mixtures will produce, so it is difficult to obtain standard results. Baking powder recipes generally are more reliable.

Salt

Very little salt is used in bread making, but the amount used is essential, for it performs a very important function. Without salt, fermentation in dough is too rapid, and the baked product is too coarse, while too much salt will slow fermentation and the bread will be soggy. Salt strengthens gluten and helps it to expand, improves the color of baked products, and enhances the flavor.

Never use more than 3 peroent salt, or you will have salty bread. More than 5 percent will kill the action of the yeast. Most bread recipes call for $1\frac{1}{2}$ percent to $2\frac{1}{2}$ percent of the weight of the flour in the recipe. Use more salt to strengthen a weak gluten and for rich doughs. If you wish to reduce the speed of the fermentation, you can accomplish this by the use of more salt. The salt in the loaf makes it less likely to become moldy.

Sugar

In a bread dough, sugar is added to give the yeast an energy food as a source of carbon dioxide gas. Most of the sugar in breads, however, is converted from the starch by enzymes in the dough.

This sugar in the bread contributes to the color of the crust, the taste of the baked loaf, the toasting qualities of the bread, texture, moisture retaining qualities, and the nutritional value. Sugar is also a tenderizer.

All sugars do not have the same degree of sweetness, since sweetness depends upon the refining process through which the sugar has passed. Brown sugar, for example, is less highly refined than white sugar, and therefore is not so sweet. Brown sugar lends a pleasant taste to cooked or baked products, and sirups can be used for cakes and cookies. Sugar sirup is often used as a substitute for regular sugar. Corn sirup, honey, or molasses improves the flavor of cookies and helps them retain their moisture.

Shortening

Shortening is any edible fat used in baking. If the shortening is solid at room temperature, it is a fat. If it is a liquid at room temperature, it is an oil. The fat type shortening is more desirable for use in bread dough, because it can be more thoroughly distributed through the dough. The reason for this is that it will not saturate the flour with which it comes in contact. The oil type of shortening can be used effectively, provided the dough is well formed before the oil is added.

Butter is thought of as shortening when it is used in baking. Actually it is not a pure shortening because it contains milk solids, salt, and moisture. When butter is used as a shortening, you should adjust your recipe so that the total milk, salt, and moisture content is not adversely increased, and the total fat content is not adversely decreased.

Some of the common types of shortening are given in the following paragraphs.

LARD is rendered fat of sound healthy hogs.

SHORTENING COMPOUNDS are composed of animal and vegetable fats mechanically blended to give a final product of acceptable plasticity and satisfactory baking quality.

HYDROGENATED SHORTENING is a combination of vegetable oils that has been transformed from oil into a solid fat, white in color and tasteless. This is a high grade shortening that has excellent baking qualities.

SHORTENING with EMULSIFIER is hydrogenated shortening to which an emulsifying agent has been added. This gives the shortening exceptional ability to blend with other ingredients.

VEGETABLE OILS are obtained commercially from cotton seed, soy beans, corn, sunflowers, and peanuts.

Shortening produces tenderness in baked products, adds flavor and richness, helps produce better grain and texture, and makes the products stay fresh longer.

Milk

Milk is one of the almost complete foods. Nonfat dry milk contains all the food qualities of milk except fat. It is most acceptable for bread production because it is almost 100 percent nonfat milk solids. Dry milk can be added by mixing or sifting the milk and flour together, or it can be reconstituted with part of the water in the bread recipe and added to the dough. In either event, it is important that there be no lumps of milk powder in the dough.

The amount of milk used in the dough can be as high as 6 percent nonfat dry milk based on the weight of the flour. Inclusion of more than 6 percent in the bread dough is detrimental to fermentation. Milk improves the texture, flavor, and keeping quality of bread.

Eggs

In baked products, eggs supply a high protein, mineral, and vitamin content. The yolks add color, the whites help bind other ingredients, and both combine to add flavor and moisture.

Fresh eggs should be removed from the refrigerator and warmed to room temperature before being used in dough. Frozen eggs should be completely defrosted before being added to the dough, and should be well mixed. Dried whole eggs may be sifted with the dry ingredients in some baked products containing a high percentage of dry ingredients; the water needed to reconstitute the eggs is added to the required liquid. In cake batters, however, best results are obtained when the dried whole eggs are reconstituted prior to using the recipe. Reconstituted eggs should be used within 1 hour unless refrigerated. Do not hold them overnight.

BAKING TERMS

In addition to learning how to use the tools of your trade, you will need a speaking and working knowledge of the terminology that bakers use. The following terms will help you understand baking directions and recipes, and will enable you to know what other bakers are talking about when they use them.

ABSORPTION OF FLOUR is a commonly used term which refers to the ability of flour to absorb and hold liquid. Different flours vary in their ability to absorb liquid, and therefore there is a variation in the amount of water necessary to produce dough of normal consistency from a definite amount of flour. Absorption is expressed in percentages. For example, flour that will absorb 60 pounds of liquid for every 100 pounds of flour has an absorption power of 60 percent. The quality of flour is indicated by the amount of liquid it will absorb. Navy issue flour absorbs from 60 to 75 percent, which is very high.

When you don't know how much liquid a certain type of flour will absorb, you can take 1 pound of flour, add water to make the type of dough you want, weigh the dough, subtract 1 pound, and the remaining weight will be the amount of liquid absorbed. Use this weight to determine how much liquid you will need for your entire batch of flour.

FERMENTATION is the chemical change that takes place when yeast (or other leavening agent) in the bread releases carbon dioxide gas, causing it to rise. The fermentation period is the time which elapses between the mixing of the dough and the time the yeast is killed by the oven heat (140°F).

DIVIDING means cutting the dough into suitable size for scaling.

SCALING is the weighing of each piece of dough after it has been divided, to make sure each is the same size. An accurate set of scales is necessary for scaling bread.

ROUNDING UP, or BALLING UP, means rolling the divided pieces of dough into balls to close up the cut sides of the dough.

MOLDING, or MAKEUP, of dough means to form the dough into loaf shapes for proofing. The round ball of dough is rolled and flattened, and at the same time, lengthened until it is long enough to fold over its own length. Fold the dough and press it firmly with the heels of your hands to press out the gas. Roll it tight, compact, and free from air pockets.

8628

PUNCHING, CUTTING OVER, and TURNING all refer to the same operation, which takes place after the dough has risen the first time. The dough is punched to release the gas and is folded over. Then the dough is allowed to rise again and ripen.

PROOFING or PANPROOFING is the process by which the fermentation of the dough is completed in a proofing cabinet, where the temperature and humidity are controlled. This will take about 1 hour under normal conditions.

PANNING means to place the molded loaves in pans.

BREAD

Bread is the most important food produced by the baker. He prepares it in greater quantity than any other baked product. High quality and excellent taste must be maintained, regardless of the amount of bread you are required to bake.

After you select and weigh or measure the necessary ingredients, the next important step is mixing. Dough must be mixed thoroughly to make it smooth, to distribute the ingredients evenly, and to develop the gluten fully. Dough may be mixed by hand, but an electric mixer or a bread-dough machine will make your job easier. Time and speed of mixing vary with the type of mixer used, the kind of dough being prepared, and the strength of the flour.

Fermentation

Fermentation commences as soon as the dough is mixed, and continues until the yeast is killed by the heat of the oven. The correct temperature for the dough during fermentation is indicated on the Recipe Service recipe card. A higher temperature will cause growth of undesirable bacteria (wild yeast) and excessive acidity, which result in a coarse-grained bread of poor flavor.

The length of the fermentation period depends upon the amount of yeast used, strength of the flour, and temperature during fermentation. More yeast and higher temperatures cause the dough to rise faster. Weak flours require a shorter fermentation period than strong ones. Insufficiently fermented or conditioned dough is called "young dough," while that which has fermented too long is known as "old dough."

Punching

Punching the dough after it rises develops the gluten, and also redistributes the yeast cells. The temperature of the dough is equalized, and some of the carbon dioxide gas is forced out. Straight dough must be punched or worked down as soon as it has doubled in size, the rising time for dough made with 2 percent yeast being about 2 hours at 80°F.

To test the dough to see if it is ready for punching, insert your open hand into the top of the dough about 3 or 4 inches. If the impression that is made in the dough recedes slightly, the dough is ready to be punched or folded. If the impression closes up immediately, the dough is not ready. The length of time the dough remains in the dough trough should be calculated by using a definite fermentation ratio as shown in Chapter 3 of the Baking Handbook.

Makeup

The first step in making up a dough is to divide it into small uniform portions. When dough is divided by machine, you won't have a worry about size; but when you divide it by hand, it must be scaled to make sure each piece is the same size. When dividing dough, allow for loss in the baking process. This baking loss is approximately 10 percent of the total weight before baking.

After the dough has been divided, it must be rounded into balls to prevent escape of carbon dioxide gas through the cut edges of the dough.

A period of intermediate proofing follows the rounding process. During this time, the dough is allowed to rest and recover from being divided and rounded. It becomes loose enough so that it can be easily handled. The length of time of the intermediate proofing period is indicated on the recipe card.

Use as little dusting flour as possible, and follow these steps:

1. Place each piece of dough on the board, top side down.
2. Press gas out of dough (see fig. 11-6, upper left), and pull lengthwise carefully, shaping the dough into an oblong about the length of a finished loaf of bread.
3. Flatten dough with your hands or with a rolling pin.
4. Shape the dough by folding in the ends to form a rectangle. (See fig. 11-6, upper center.)
5. Fold lengthwise (fig. 11-6, upper right) to the center and seal (fig. 11-6, lower left) by firm finger pressure.
6. Fold over the other half of the dough (fig. 11-6, lower center) and press for additional seal.

8629

7. Roll dough (fig. 11-6, lower right) to complete sealing and molding of the loaf.

After the dough is molded into a loaf, place it in a lightly greased baking pan. Each loaf should be placed so that the molding seam is on the bottom, and the loaf should be long enough to reach the ends of the pan.

Proofing

Letting the dough rise at this stage is known as pan proofing. Since most of the gas was expelled from the dough in the molding process, the loaves will rise again to the proper degree of lightness.

Bread should be proofed until it doubles in size which will normally take 1 hour. Make sure the dough rises sufficiently, or you will have small loaves of heavy bread. Excessive proofing, on the other hand may cause a loaf to fall, be irregular in shape, and be coarse in texture. The temperature to be maintained during this period of proofing is indicated on the recipe card.

Baking and Cooling

Baking time for breads and pastries varies with the size of the pan and the amount of dough scaled into each pan. When the oven is fully loaded, the bread will not bake as rapidly as in

Figure 11-6.—Making up bread dough.

48.53

8630

a lightly loaded oven. Correct oven temperatures must be maintained if you expect your products to be baked properly.

Place the pans of dough in the oven carefully, because a jolt will affect the body of the dough. Remember the order in which the pans were placed in the oven; the first placed in should be the first to be removed. Make sure all pans are properly spaced so that the bread can be baked on all sides.

When it is necessary to bake the bread before it has risen sufficiently, the temperature of the oven should be lowered for a brief period to allow it to rise while the baking is in progress. During the first few minutes in the oven, the dough will rise rapidly; such a rise is known as "oven spring."

When the bread is done, remove from the pans, and place on racks to cool, making sure there is at least a 1-inch space between loaves. Cooling usually takes from $1\frac{1}{2}$ to 2 hours. Bread should not be covered while it is warm.

Rope and Mold

ROPE is an undesirable condition of bread caused by bacteria. The crumb of the loaf deteriorates, darkens, and becomes sticky and wet. If the loaf is pulled apart, long, wet strands will appear as it separates. Rope has an odor similar to overripe cantalope.

The rope spores that are formed from the active rope bacteria cells are highly resistant to heat, and any that may be near the center of the loaf are not killed during the baking. Therefore, only the proper conditions and sufficient time are necessary for their activation and appearance in the baked bread.

Temperatures of 86°F and above, particularly temperatures of 95°F to 105°F, promote the development of rope. When the climatic condition is such that the shop temperature is high, rope could develop in doughs that are even lower than 85°F. In the Tropics, high humidity often accompanies high temperature. This increases the danger of rope developing in the bread. Also doughs that are not sufficiently acid are highly subject to rope infection. Since acidity is normally increased through fermentation, an overly warm dough may not have time to become sufficiently acid to retard the development of rope.

When the weather or climate is hot and humid, you should keep a sharp lookout for the appearance of rope, and do everything in your power to prevent its development. By controlling the temperature of the doughs, you can make them cold enough to retard the development of rope.

Keeping equipment scrupulously clean and seeing that no pieces of previous doughs are allowed to remain in the shop, will also help prevent rope. The shop and all equipment should be thoroughly cleaned as soon after use as possible.

Ingredients should not be kept in the shop longer than necessary, and those that are kept should be arranged to allow free circulation of air around them. The bread baking schedule should be planned so that bread is not overstocked and allowed to become old in the shop or in the storage room. Bread that has accumulated and has become stale may be used for croutons and crumbs. All bread should be thoroughly cooled before being stored.

Vinegar may be used in the dough to increase its acidity and help prevent rope. Normally a proportion of 1 percent of 45 grain vinegar, to the weight of the flour, is sufficient. This amount may be increased up to 2 percent if it is felt that the danger of rope is a real hazard. The vinegar should be added during step 1 of the Navy-Marine Corps Recipe Service recipe for white bread, shown in figure 11-4. The dough may be made slightly stiffer by using less water. The amount of yeast used in the dough should be increased so that fermentation will progress at a vigorous rate, even with the dough temperature lowered, and the dough stiff.

In the event that rope does develop in your shop, it will be necessary to kill all the rope bacteria there before you do any more baking. Dispose of all baked products and ingredients in the shop, and thoroughly clean the shop and all the equipment. This means washing the bulkheads, decks, and overhead with hot soapy water and rinsing; removing all foreign matter from all equipment and tools and from the cracks and seams in the oven; sterilizing the work bench and all small equipment; and rinsing down everything a second time with a strong vinegar and water solution. When the production of bread is started again, use 2 percent vinegar in the doughs.

MOLD is composed of tiny plants visible to the naked eye. There are many types of mold which vary in form and color. They form velvety, colored spots on the bread and create a musty odor. Mold spores are present in the air and will become visible on almost any food substance if they are given sufficient time under proper conditions. Mold will multiply in a warm, humid atmosphere or on moist food. The absence of

SWEET DOUGH C. BREADS No. 28 (1)

YIELD: 100 Portions EACH PORTION: 1 Roll (2 Ounces)

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Yeast, active, dry Water, warm (110° F) Sugar	3 oz ..... 1 oz	10 tbsp 3/4 qt 2 1/4 tbsp	....	1. Sprinkle yeast on top of water. Let stand 5 minutes, then stir. Add sugar, stir until dissolved. Let stand 10 minutes longer, then stir again.
Milk, nonfat, dry Sugar Salt Mace (optional)	4 3/4 oz 15 oz 1 1/2 oz	1 cup 2 1/8 cups 3 tbsp 1 tsp	....	2. Mix and sift milk, sugar, salt, and mace into mixer bowl.
Shortening Vanilla	1 lb 2 oz	3/4 qt 1/2 tsp	....	3. Add shortening and vanilla, cream until smooth.
Eggs, whole, slightly beaten	1 lb 2 oz	11 eggs (1 1/8 pt)	.....	4. Blend in eggs.
Water (68° F) variable	.....	5 1/4 cups	.....	5. Blend in water.
Flour, hard wheat, sifted	6 lb	6 qt	.....	6. Add flour and start mixer on low speed. Immediately add yeast suspension, mix until flour is thoroughly moistened. 7. Mix on medium speed approximately 15 minutes or until dough is smooth and elastic. 8. FERMENT: Approximately 1 3/4 hours or until almost double in bulk at a dough temperature of 80° F. 9. PUNCH: Divide dough into desired working-size pieces. Round up and let rest 15 minutes.
				10. MAKE UP: As desired. 11. PROOF: Until pieces are double in size. 12. BAKE: 10 to 15 minutes at 425° F. 13. FINISH: As desired.

NOTE: 1. To perform Step 10, see Guide for Sweet Dough Make Up, Recipe Card C–G–2.

2. 6 oz compressed yeast may be substituted for the active dry yeast in Step 1.

3. Dried whole eggs may be substituted for the whole eggs in Step 4. See Recipe Card A–5. Increase the water in Step 5 to the required amount; sift the dried eggs with the flour in Step 6.

4. In Step 6, 3 lb 10 oz soft wheat flour may be substituted for the 6 lb sifted hard wheat flour. This 60/40 ratio of flour produces a lighter sweet dough product.

Figure 11-9.—Recipe for sweet dough. 48.47.8

8634

light and sufficient time also contribute. Mold first appears on the side of a loaf.

Mold is not resistant to heat, and therefore mold that may be present in ingredients will probably be killed during baking. This means that any mold on bread is a result of improper handling of the baked loaf.

Mold can easily be prevented in the bakeshop. The shop should keep clean and dry. Proper circulation of air should be ensured. Dark areas should be lighted. The loaf should be thoroughly baked and properly cooled before storing. Always avoid handling it with wet or damp hands. See that it is not necessary to keep bread for any length of time, since bread molds very quickly in storage.

Rolls

The recipe in the Navy-Marine Corps Recipe Service which applies to most types of hot rolls is shown in figure 11-7 (page 176). A number of types of hot rolls can be made from this basic recipe.

The method of making rolls is the same as that used for making bread. However, less mixing is required and the dough is much softer. Careful handling of the dough and developing skill in handling it will ensure light, tender rolls.

In make-up, the dough is divided into 3 or 4 pound pieces. Each piece of dough is then rolled into a strip $1\frac{1}{2}$ inches in diameter. The strips of dough are cut into pieces weighing approximately 2 ounces each (fig. 11-8A). These pieces are then rounded into balls by rolling them with a circular motion on the work bench (fig. 11-8B). When these basic steps are performed, you are ready to shape the dough into sandwich rolls (fig. 11-8C), parker house rolls (fig. 11-8D, E, and F), weiner rolls (fig. 11-8G), and dinner rolls (fig. 11-8H).

Sweet Rolls

A wide variety of sweet rolls can also be made from the simple basic sweet dough recipe. After you have mastered the basic mix, you are well on your way to becoming a good baker.

The basic recipe for sweet dough from the Navy-Marine Corps Recipe Service is shown in figure 11-9. The dough should be smoother than bread dough, but it should not stick to your hands.

Among the types of sweet rolls that can be made from this basic recipe are cinnamon buns, butterfly rolls, double-leaf rolls, pecan rolls, twists, chain twists, braids, bear claws, crullers, snails, crescents, raisin buns, hot cross buns, plain coffee cake, small coffee cakes, and Swedish tea rings. Specific instructions for making each of these types of sweet rolls from the basic dough recipe are given in the Navy-Marine Corps Recipe Service. Some of these rolls are illustrated in figures 11-10, 11-11, and 11-12.

Much of the attractiveness of sweet rolls is furnished by the glazes and fillings used. You will find the recipes for these glazes and fillings in the Navy-Marine Corps Recipe Service—Frostings and Fillings.

BAKING POWDER BISCUITS C. BREADS No. 1 (1)

YIELD: 100 Portions EACH PORTION: 2 Biscuits (2¼ Ounces Each)

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Flour, hard wheat, sifted	13 lb	3¼ gal		1. Mix and sift flour, milk, baking powder, and salt into mixer bowl.
Milk, nonfat, dry	2½ lb	2 qt		
Baking powder	10 oz	1½ cups		
Salt	¼ lb	7 tbsp		
Shortening	5 lb	3 qt		2. Add shortening. Mix on low speed approximately 1 minute or until mixture resembles coarse corn meal.
Water		4¼ qt		3. Gradually add water and mix on low speed approximately ½ minute or until dough is just formed. DO NOT OVER-MIX. 4. Place portion of dough onto lightly floured board. Knead lightly approximately 1 minute or until dough is smooth. 5. Roll out to a uniform ½ inch thickness. 6. Cut with a 2½ inch floured cutter. 7. Arrange biscuits close together on lightly greased baking sheets (18 by 26 inches). 8. Bake at 425° F 12 to 15 minutes.

NOTE: If time and space are limited, the dough may be cut in squares. This will eliminate re-rolling dough.

VARIATIONS C. BREADS No. 1 (2)

1. BUTTERSCOTCH BISCUITS: Roll dough into a rectangular sheet ⅓ inch thick. Spread with melted butter and brown sugar. Roll dough as for jelly roll. Cut into slices ¾ inch thick. Place cut side down, approximately 1 inch apart, on greased baking sheets (18 by 26 inches).

2. CHEESE BISCUITS: Decrease shortening to 4½ lb. Add 2 lb (2 qt) grated cheddar cheese before adding the water. Brush with milk and sprinkle with grated cheddar cheese.

3. CINNAMON BISCUITS: Proceed as for Butterscotch Biscuits. Spread with approximately 4 qt Cinnamon Sugar Mix. (See Recipe Card I-24.)

4. DROP BISCUITS: Use additional cup of water. Drop by tablespoonfuls onto greased baking sheets, approximately 1 inch apart.

5. ORANGE BISCUITS: Add grated rind of 12 oranges in Step 3. Make a small indentation in each biscuit and top with ½ tsp of orange marmalade.

6. CORN MEAL BISCUITS: Substitute 3½ lb (10½ cups) corn meal for 3½ lb (3½ qt) of flour in Step 1.

48.47.9

Figure 11-13.—Recipe for baking powder biscuits.

8636

Quick Breads

Quick breads include griddle cakes, waffles, popovers, muffins, and biscuits. They are called quick breads because a quick-acting leavening agent, baking powder or baking soda, is used, and a comparatively short time is required to mix and bake them.

There are two kinds of batters, soft or muffin batter, and roll-out or biscuit dough. If the product is to be muffins, griddle cakes, popovers, or waffles, the recipe will make a soft batter that may be spooned or poured. If the batter is to be rolled or cut for baking powder biscuits, the mix will require a lower proportion of liquid. The mixing of the batter is always kept to the very minimum when the leavening is produced by baking powder or baking soda.

The basic Navy-Marine Corps recipe for baking powder biscuits is given in figure 11-13. Note that if time and space are limited, the dough may be cut into squares instead of circles (see fig. 11-14). This eliminates re-rolling. Also, in order to plan work, biscuits may be panned and placed in the refrigerator 1 hour or more before baking time. This does nct mean, of course, that they can be held indefinitely before baking.

Recipes in the Navy-Marine Corps Recipe Service outline, step by step, the method for mixing quick bread batters.

CAKES

Two main types of cakes you will most likely be called upon to bake are batter and foam, the difference between them being that foam cake is made without shortening. The two main types are often combined to give you a third type, chiffon. In this type, the batter part and the foam part are mixed separately and then the batter is folded into the foam (or vice versa) to form the finished batter or mixture called "CHIFFON."

48.58

Figure 11-14.—Cutting biscuits.

Each ingredient in a basic recipe has a specific function.

FLOUR furnishes structure and is used to hold the other materials together in making cake and should be soft wheat flour.

SUGARS, used chiefly as sweeteners, have tenderizing effects resulting from their ability to soften flour protein and starches. By lowering the caramelization point of the batter, sugars allow the cake crust to color at a lower temperature. Sugars also help to retain moisture in the baked cake, thereby keeping the cake moist and edible for several days.

SHORTENING carries the air incorporated in the finished cake batter; this air has a tenderizing action on the cake by virture of its leavening action. Shortening makes the baked product tender and must be considered to be a tenderizing agent.

EGGS furnish structure, moisture, flavor, and color. Egg whites for whipping must be free from grease or traces of egg yolk — as little as one-tenth of one percent will adversely affect whipping quality.

MILK, water, fruit juice, or coffee can be used as liquid in cake. Liquid is needed to combine and activate all other ingredients. It controls the consistency of the finished cake batter.

SALT brings out the flavor of the other ingredients used in the cake.

LEAVENING is accomplished in three ways: incorporation of air during mixing, chemically leavening, and vaporization of liquids in the dough by the heat of the oven. The manner of leavening depends upon the type of cake being made in regard to richness of formula, consistency of batter, and baking temperature.

In addition to the proper selection of ingredients, accurate measuring, and thorough mixing, three factors influence the finished baked products:

PANNING is the amount of batter used in a pan of given diameter and depth. It helps to determine whether the cake is moist or dry. The batter should be divided evenly by scaling or by use of a measure, then spread evenly in the pan with a spatula. Do not rap the pan on the work table to level the batter.

8638 8637

BAKING TEMPERATURE is of the utmost important for it determines the texture of the baked product. The oven temperature and baking time vary with the type of product to be baked. The recipes in the Navy-Marine Corps Recipe Service note the correct oven temperature and baking time for the various types of baked products.

COOLING of the cakes before removing from the pan or icing is important. The time will vary with the thickness of the cake and the room temperature, but a minimum of 30 minutes should be allowed.

The Navy-Marine Corps Recipe Service recipe for a plain cake made with shortening is shown in figure 11-15. Variations of this cake may be made by adding fillings, frostings, or sauces. Recipes for the variations are included in the Recipe Service.

Frostings.—Frostings make a cake more tasty, increase eye appeal, and add food value. The terms

BASIC PLAIN CAKE D. CAKES AND COOKIES No. 1

YIELD: 100 Portions EACH PORTION: Cut Each Pan 6 by 9

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Flour, soft wheat, sifted	4 lb	4¾ qt		1. Sift together flour, sugar, baking powder, and salt into a mixer bowl.
Sugar	4 lb	2¼ qt		
Baking powder	3 oz	½ cup		
Salt	1½ oz	3 tbsp		
Shortening	1½ lb	¾ qt		2. Blend in shortening on low speed for 1 minute.
Eggs, whole, beaten	1½ lb	15 eggs (1½ pt)		3. Mix together eggs, milk, and vanilla. Add ⅓ of the mixture, mix on medium speed for 3 minutes; add another ⅓ of mixture, mix on medium speed for 3 minutes. Then add the remaining ⅓ of mixture, mix on medium speed for another 3 minutes. Scrape sides of bowl well after each addition.
Milk, liquid, whole		6½ cups		
Vanilla		2 tbsp		
				4. Scale 7 lb (approximately 1 gal) of batter into each greased and floured baking sheet (18 by 26 inches).
				5. Bake at 375° F until done, approximately 25 minutes.

NOTE: 1. Dried whole eggs may be substituted for the whole eggs in Step 3. See Recipe Card A-5. Sift the dried eggs with the dry ingredients in Step 1; add the required amount of water in Step 3.

2. Evaporated milk, dry whole or dry nonfat milk may be substituted for the liquid whole milk in Step 3. See Recipe Card A-4. Sift the dry milk with the dry ingredients in Step 1; add the required amount of water in Step 3.

48.47.10

Figure 11-15.—Recipe for a plain cake.

8638

FROSTING and ICING are used interchangeably. Some frostings are used also for fillings, but often fillings are an entirely different substance.

Don't try to be too artistic when it comes to frostings. Rich cakes require simple frostings, while plain cakes may be more elaborately iced. Frostings may be cooked or uncooked, depending on the texture of your cake. Remember it is unsanitary to get your hands in a frosting, especially an uncooked one.

The Navy-Marine Corps recipe for vanilla cream icing, which is uncooked, is given in figure 11-16. Butter cream is the richest of all frostings. The Navy recipe for cooked frosting is given in figure 11-17.

COOKIES

Cookies are a popular dessert. Unlike most other desserts they can be stored a day or more and used as needed. Successful cookies depend upon proper mixing of ingredients; clean, dry baking pans; and correct baking temperature.

Cookies are of five types; rolled, dropped, ice box, sheet, and bar. Cookie dough should be mixed just enough to incorporate the ingredients thoroughly.

The dough for rolled cookies usually is as soft as can be handled. It may be more easily rolled if it is chilled before being used. Rolling a small part of the dough at one time facilitates handling and lessens the amount of rerolling. The dough is usually rolled to a thickness of $^1/_4$ inch and cut with a 2-inch floured cutter. The side of the spatula should be used for removing cookies from the board to the baking sheets.

Dropped cookies are made from a soft dough. The consistency determines whether the cookies will be rough and flat or hold their shape. Dough is dropped on greased floured baking sheets.

When making ice box cookies, cut the dough into 10-ounce pieces and shape into rolls as for bars. Each roll is wrapped in waxed paper, placed in a pan, and chilled or refrigerated overnight. To make ready for baking, chilled rolls are sliced with a knife or electric slicer.

Bar cookies are made of dough rolled into a strip 22 inches in length or to fit the sheet pan. Fold the two ends of the strip toward the center in order to move to the baking sheet. Allow space between strips. Use your fingers to shape the dough in uniform $^3/_4$-inch strips. Brush with egg wash, if desired. After bars are baked and cooled, cut them diagonally into pieces about two inches in width.

When making sheet cookies spread batter into shallow greased pans. Bake in a moderate oven. Cut into squares or strips while still warm. Coat with powdered sugar if desired. Recipes in the Recipe Service outline step by step methods for preparing all types of cookies.

The pans used for baking cookies should be clean, dry, and smooth. They should be greased and floured for cookie dough high in moisture, greased for average rich dough, and left ungreased for dough rich in shortening. Examine

VANILLA CREAM ICING — I. FROSTINGS AND FILLINGS No. 3

YIELD: 2 Quarts or 100 Portions — EACH PORTION: 1 Quart Per Sheet Cake

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Butter or shortening	10 oz	1¼ cups		1. Cream butter or shortening and vanilla until light and creamy.
Vanilla		2 tbsp		
Sugar, confectioner's, sifted	2½ lb	2½ qt		2. Gradually add confectioner's sugar, salt, and evaporated milk.
Salt	¼ oz	1½ tsp		3. On high speed, whip for approximately 5 minutes or until mixture is fluffy and smooth.
Milk, evaporated		1 cup		

NOTE: The volume of icing will vary depending upon the amount of creaming.

VARIATIONS

1. CHOCOLATE CREAM ICING: Add 4½ oz of cocoa sifted with the sugar. Increase evaporated milk by 3 tablespoons.
2. LEMON CREAM ICING: Omit vanilla. Use ¼ cup of lemon juice for ¼ cup of milk, and add ½ oz (1½ tbsp) of grated lemon rind.
3. ORANGE CREAM ICING: Omit vanilla. Use 6 tablespoons of orange juice for 6 tablespoons of evaporated milk, and add 1 oz (2 tbsp) of grated orange rind.

Figure 11-16.—Recipe for vanilla cream icing. 48.47.11

8639

COOKED FROSTING — I. FROSTINGS AND FILLINGS No. 1

YIELD: 100 Portions (2 Quarts) — EACH PORTION: 1 Quart Per Sheet Cake

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Sugar Salt Cream of tartar Water	3/4 lb	1 3/4 cups 1/8 tsp 1/4 tsp 1 cup		1. Combine sugar, salt, cream of tartar, and water. Cover, bring mixture to a boil. 2. Remove cover and cook until sirup spins a 2 inch thread (234° F). DO NOT STIR.
Egg whites (room temperature)	7 oz	8 egg whites		3. Beat egg whites until foamy.
Sugar, confectioner's sifted	5 oz	1 1/4 cups		4. Gradually add 1/2 of the confectioner's sugar, beat until whites "peak." 5. Slowly pour the hot sirup over the stiffly beaten egg whites, while beating on high speed. DO NOT SCRAPE the sirup kettle.
Vanilla		1 tbsp		6. Add vanilla and remaining confectioner's sugar. Beat thoroughly.

48.47.12

Figure 11-17.—Recipe for cooked frosting.

the pans carefully before using them to avoid trouble later with sticking or uneven baking.

Baking at the correct temperature for the correct length of time is very important. Most cookies are baked at temperatures between 350°F and 400°F. Cookies should be on the soft side when taken from the oven, for the dough will bake a trifle during the cooling period.

PIES

The success of any pie depends first on the crust. A tender pie crust depends on the ingredients used and on careful mixing.

SOFT WHEAT FLOUR makes a tender crust that crumbles easily.

Fats vary in their ability to produce flaky pastry. LARD and HYDROGENATED FATS are 100 percent fat and make the tenderest pastry.

WATER acts as a binder to the other ingredients. The amount of water required will vary with the kind and temperature of ingredients and the extent to which the fat and flour are blended. Dough that contains too much water is well bound and the baked crust will not be tender. Dough that contains too little water is not sufficiently bound and the baked crust will be crumbly.

SALT has a desirable binding effect upon the dough. It develops and enhances the flavor of the other ingredients.

The fat should be mixed with the flour until the mixture resembles coarse corn meal with small particles of fat distributed evenly through the mixture. This may be done on the electric mixer with a pastry knife attachment or by mixing lightly with the fingers. The extent to which the fat and flour are blended largely determines the quality of the crust. Overmixing at this stage will make a paste of the fat and flour, and it will be impossible to add the water required to bind the ingredients together. Excessive mixing after the water has been added will result in a tough crust.

When the dough has been mixed, it should be set aside for a few hours in a cool place. This gives the flour time to hydrate properly and allows the dough to cool. Dough should be given the minimum amount of handling during makeup.

DIRECTIONS FOR MAKING A TWO-CRUST PIE K-G. PASTRY AND PIES No. 2

1. DIVIDE DOUGH:
   Divide dough into pieces of a size easily handled and place on a lightly floured board. Roll each piece into a cylinder approximately 3 inches in diameter, handling as little as possible. Cut into 8 ounce pieces for the bottom crust and 7 ounce pieces for the top crust.

2. ROLL DOUGH:
   Sprinkle each piece of dough lightly with flour; flatten gently. Using a floured rolling pin, roll lightly from center out to edge, in all directions, forming a circle approximately 1 inch larger than pie tin and approximately ⅛ inch thick. Shift or turn dough occasionally to prevent sticking to board.

3. BOTTOM CRUST:
   Fold pastry circle in half; lift onto ungreased pie pan, with fold at center; unfold and fit carefully to eliminate air pockets; bounce lightly on board to help free trapped air.

4. FILL CRUST:
   Arrange approximately 3½ cups of prepared filling in lined pie pan.
5. TOP CRUST:
   Roll top crust in the same manner as bottom crust. Fold in half; with knife, make several slits near center fold to allow steam to escape during baking. Brush outer rim of bottom crust with water. Lay top crust over filling, with fold at center; unfold and press edges of two crusts together lightly.
6. REMOVE EXCESS DOUGH:
   Trim the overhanging edges of dough by pressing hands against rim of pie pan. There should be little excess dough if skill is used in gauging portions and rolling. Use dough trimmings for bottom crust only.
7. SEAL PIE:
   Press edges firmly together or finish crust with a fluted edge. To help prevent juice from overflowing around edges of pie, lift sealed edges of pie with edge of a knife.
8. GLAZE TOP:
   If a glazed top is desired, brush top with water, milk, melted butter or Egg and Milk Wash (Recipe Card K-4). Allow glaze to dry on pie before placing it in oven. This eliminates dark spots.
9. BAKE:
   Bake at 425° F approximately 45 minutes or until crust is nicely browned. The exact time will vary with the filling used in the pie. The pie is done when the juice just begins to boil out of the perforations.

48.47.13

Figure 11-18.—Directions for making a two-crust pie.

S130 8641

DIRECTIONS FOR MAKING A ONE CRUST PIE — K-G. PASTRY AND PIES No. 1

BAKED PIE SHELL:

1. See Recipe Card K– Make up half the recipe; divide dough into pieces of a size easily handled and place on a lightly floured board. Roll each piece into a cylinder approximately 3 inches in diameter, handling as little as possible. Cut each roll into 7½ ounce pieces.
2. ROLL DOUGH:
   Sprinkle each piece of dough lightly with flour; flatten gently. Using a floured rolling pin, roll lightly from center out to edge, in all directions, forming a circle 1 inch larger than pie pan and approximately ⅛ inch thick. Shift or turn dough occasionally to prevent sticking to board. If edges split, pinch cracks together.
3. PLACE CRUST:
   Fold rolled dough in half and carefully place into ungreased pie pan. Unfold and ease into pie pan, being careful not to leave any air spaces between pan and dough. A light bounce on the board will help to eliminate trapped air.
4. REMOVE EXCESS DOUGH:
   Trim ragged edges approximately ½ inch beyond edge of pan. Fold extra dough back and under, and crimp with the thumb and forefinger to make a high fluted edge. Dock or prick dough on bottom and sides to prevent puffing.
5. BAKE:
   Bake at 450° F approximately 10 minutes or until golden brown. If available, place an empty pie pan inside of shell before baking to help prevent shrinking and puffing.

UNBAKED PIE SHELL:

1. Follow Steps 1 through 4, omitting docking of dough.
2. Fill and bake in accordance with specified recipe.

48.47.14

Figure 11-19.—Directions for making a one-crust pie.

The dough can be used for double crust pies, for custard-type using an unbaked shell, or for prebaked shell type. The Recipe Service includes guidance cards which outline directions for making a two-crust and a one-crust pie. See figures 11-18 and 11-19.

The standard pie crust, properly made, has outstanding characteristics. In appearance, it is golden brown with a rough surface that appears blistered. The texture may be flaky or mealy depending upon the method used to combine the ingredients. It should be tender enough to cut easily, but not so tender that it breaks or crumbles. The flavor should be delicate and pleasing.

48.59

Figure 11-20.—Shaping the turnover.

Turnovers

Turnovers can be made from pie crust dough, following these steps:

1. Roll dough into a rectangular sheet $^1/_8$ inch thick.
2. Cut into 5- or 6-inch squares.
3. Place 3 tablespoons of thick fruit filling in the center of each square.
4. Brush edge with water and shape turnovers as follows:
   a. Fold to form a triangle and seal edges, or,
   b. Fold opposite four corners to center, and seal by crimping edge, as shown in figure 11-20.

Meringue

Meringue will add to the attractiveness of a one-crust pie. The Navy-Marine Corps recipe for meringue is shown in figure 11-21. Beat the meringue mixture until it is light, and spread it evenly over the top of the pie, so that it touches

MERINGUE K. PASTRY AND PIES No. 5

YIELD: 100 Portions (Topping for 17 (9 inch) Pies) EACH PORTION: 2 Cups per Pie

INGREDIENTS	WEIGHTS	MEASURES	PORTIONS	METHOD
Egg whites, room temperature	2¼ lb	42 egg whites (4½ cups)		1. Beat egg whites, salt, and vanilla until foamy, using high speed, approximately 1 minute.
Salt	¼ oz	1½ tsp		
Vanilla	½ oz	1 tbsp		
Sugar	2¼ lb	1¼ qt		2. On medium speed add sugar, a little at a time. Beat well after each addition. Beat until egg whites just hold their shape, approximately 6 minutes.
				3. Spread meringue to edge of crust so top of pie is completely covered. Leave meringue somewhat rough on top.
				4. Bake at 350° F for 16 to 20 minutes.

NOTE: 1. For an equivalent yield, mix 6 ounces of meringue powder with 1 quart of cold water. Whip on high speed until stiff. Gradually add 3 pounds (1¾ qt) sugar and continue whipping for one minute.

2. To prevent shrinkage, spread meringue so that it touches inner edge of crust all around.

48.47.15

Figure 11-21.—Recipe for meringue.

the crust on all sides. It usually takes about 5½ ounces of meringue to cover a 9-inch pie. Dip your knife in warm water before cutting a meringue pie, to prevent the meringue from sticking to the knife.

REFERENCE MATERIAL

Refer to the Food Operations Reference Manual (NavSandA Publication 421) for detailed coverage of all phases of baking.

CHAPTER 12

FOOD SERVICE

Any meal, however plain, is improved by good service, and the best meal in the world can be ruined by failure to serve it properly. When you have to interest the same group of men in three meals a day, every day of the year, it is especially important to make each meal as attractive as possible. Fortunately, many of the procedures that promote sanitary and efficient service also help to keep the food attractive.

Sanitary and efficient food service begins in the galley when the food is prepared. Attractive food comes out of the galley looking and smelling good. It is brought to the serving line in appropriate containers. It is served neatly and in attractive portions by messmen who are neat and clean. The serving lines and all the serving operations are arranged to enable the hot food to be eaten hot, the cold food cold, and all foods while they are fresh and most palatable.

PREPARATIONS IN THE GALLEY

Food should always look attractive, both on the serving line and as an individual portion. This does not justify expenditure of time and materials on elaborate decoration. It does require thoughtful planning of the combination and garnishing of food, judicious selection of the most suitable serving containers, and careful serving.

Garnishes

Though garnishing is just one step in presenting food attractively, it is a very important one. A garnish is described as an ornament and also as something added for flavor or relish. Some garnishes are merely a decoration; others are planned to complement the flavor and texture of the dish as well as add "eye appeal." You should not spend the Navy ration dollar on decorations; therefore, any garnish used should be edible and should be such an integral part of the food that it will not be picked off and left on the plate.

If you were to plan a garnish for every food it would be quite a job, but fortunately, all food does not need this help. Even the plainest of foods combined in a well planned menu can get by with a minimum of garnish. For example, a meal consisting of pot roast of beef, mashed potatoes, brown gravy, buttered frozen peas, celery sticks and sweet pickles, hot rolls and butter, and blueberry pie need nothing in the way of added garnish to make it attractive. The natural colors, textures, and flavor combined in this meal provide enough variety to make the meal inviting to the eye and tempting to the taste.

Many of the Navy recipes have a "built in" garnish. Good examples of these are: (1) beef stew with vegetables; (2) tossed vegetable salads; (3) crusty browned casseroles; and (4) desserts such as cakes iced with frosting that complements the color and flavor of the cake.

Always refer to the food preparation worksheet for information regarding the garnishing of various foods on the menu.

Listed below are some practical guides to effective food garnishing:

1. Use restraint in garnishing. Keep a picture of the whole meal in mind. Too many garnished dishes in one meal will spoil the effect. Select a suitable garnish, if needed, and use it sparingly.
2. Vary food garnishes. Do not let garnishes become monotonous. (Use a section of orange or a slice of peach on top of a pudding sometimes; not always a maraschino cherry.)
3. Plan garnishes ahead and show the messman how garnished food should be served. (Should each portion have a sprig of parsley or just a few pieces be placed in the serving container?)
4. Plan simple garnishes. Do not sacrifice timely preparation for the sake of garnishing.
5. Take advantage of natural color contrasts in combining foods. Do not rely frequently on food coloring to supply color contrast.

8644

Containers

To ensure that an appetizing appearance is maintained, use shallow inserts for serving vegetables such as creamed potatoes, broccoli, and cauliflower, and for such items as breaded veal cutlets, baked pork chops, and meat in spaghetti sauce. For example, when french fried eggplant is stacked in a deep well, the first few men served will receive acceptable portions; everyone else will be served a soggy portion. If the eggplant is sent to the steamtable spread loosely in a shallow insert, you will know that all of the men served will receive as good a serving as the first man.

PREPARATIONS ON THE MESS DECK

A well-arranged serving line operates smoothly and rapidly. Each man should be able to select the servings that he wants and be able to get them to the table with the hot dishes hot and the cold dishes cold. Accomplishing these things requires planning and supervision on the part of the Commissaryman in charge.

Serving Time

The commanding officer and the supply officer establish the hours for the serving of food. The time published must be strictly adhered to; the day's work schedule in the galley must be organized to conform to the established meal-serving hours. The mess deck and the serving personnel should be ready to begin on time, and advance planning should have been done to ensure prompt and efficient service.

Posting the Menu

Service is speeded up when a person knows what foods are being served before he reaches the serving line. A good practice is to post the current menu, in full view, near the beginning of the mess line. It may be in the form of a small blackboard or typed menu. Another form is a menu board. This is a board with grooves that will hold cards bearing the names of various dishes for the meal. Any method is acceptable that gives the individual time to decide which foods he desires, or to refuse a food that he does not eat.

Preparing the Serving Line

Trays, cups, bowls, and silver, may be located at the head of the mess line, or trays cups, and bowls may be at the head of the line and the other items at the end. All items of mess gear should be inspected to see that they are spotlessly clean and should be supplied in sufficient number to last the entire serving period.

The serving counter and steamtable should be checked for cleanliness before any food is placed on them. The clean steamtable is filled with hot water and the steam turned on so that a temperature of 180°-200°F may be maintained. Always remember, the purpose of a steamtable is to keep food hot but not to cook it. Food should not remain on the steamtable for too long a time. It should be brought to the serving line in moderate quantities and replenished frequently from the main supply in the galley by the designated messman. The required temperature is difficult to maintain when the steamtable is overloaded.

Hot foods are most acceptable when eaten within the following temperature ranges:

Soups	145°-150°F
Potatoes and vegetables	140°-145°F
Entrees	140°-145°F

These foods may be held on the steamtable at temperatures higher than the 140°-150°F range to make up for the quick loss of heat while they are being carried to the table. Because whole meats retain heat longer than sliced meats, roasts should be carved on the serving line. Instructions for carving roasts are outlined later in this chapter.

Keeping cold foods, such as salads, properly chilled also requires advance preparation. Salads add so much both to balanced diet and to the general attractiveness of a menu that preparations for serving them deserve special attention. Because self-service salad bars, apart from the the hot food line, are used increasingly in the general mess, this method of serving salads is treated in a separate section later in this chapter.

The Messmen

The men who serve the food have an important effect on its attractiveness and—even more important—on its sanitary condition. Every man assigned to the serving line must be clean and look clean. That requires a fresh shave every day and hands washed many times during the day. Uniforms, hats, and aprons must be clean. When jumpers are worn, the sleeves should be rolled up to keep them from touching any food.

Messmen should not only be clean and neat; they should be trained to serve food properly,

8645

for serving techniques also effect both sanitation and attractiveness.

SERVING THE FOOD

Sending food to the steamtable in the proper container is not the only answer to good food service. What happens to the food at the steamtable, and especially how it is served, are also very important.

Serving Techniques

You as a Commissaryman or a Commissaryman striker may be placed in charge of one of the serving lines. When this is the case, you should instruct the messmen on the order of items on the serving line, how each item is to be served, and where each item is to be placed on the mess tray. Correct serving techniques should be taught for serving each item.

Soups and Similar Foods.—Soup is sent to the steamtable in deep well inserts; use the 6-ounce ladle and serve as follows. Key serving points follow each step.

1. Pick up the soup ladle.
   Hold the ladle with the right hand, about half way down the handle, grasping it between the thumb and forefinger. This is a firm hold that makes it easier to balance a full ladle.
2. Stir the soup.
   Stirring distributes the solid particles and the temperature evenly.
3. Dip from the bottom.
   Solids settle to the bottom, and the soup at the bottom of the pot is the hottest. Dip while solid particles are in motion.
4. Raise the ladle above the level of the soup bowl.
   The man in line has extended his tray and soup bowl toward you. As you raise the ladle, the liquid it contains will settle so that it is easier to pour and it will not spill over the sides.
5. Serve.
   Tip the ladle slightly and pour slowly. Direct the pouring into the center of the soup bowl.

Whenever you serve stew, chili con carne, or chow mein or any item that is similar, you should use the same technique—stirring to distribute the solid particles and the liquid evenly—then dip from the bottom.

The two points—stir and dip from the bottom are important techniques that are used when serving other menu items like creamed carrots or string beans. Each time you put your serving utensil into the container to dish up a serving—remember—stir and dip from the bottom. But, this is the ONLY TIME you should stir these items. When there is a lull and you are waiting for the next man to come through the line, do not stand and idly stir the vegetables. The least amount of handling helps maintain their appetizing appearance.

Solid Foods. As you serve items that are in shallow inserts, like macaroni and cheese or lyonnaise potatoes, serve the food from the back of the pan towards the front in an orderly system across the pan. A uniform way of serving helps maintain the fresh appearance of the food and prevents the "hashed up" look.

Carving

Carving plays an important role in serving meats in an appetizing manner. The appearance, texture, and portion size can be controlled by carving. For this reason, it is essential that Commissarymen develop the skill of carving. This can be done more readily by knowing the principles involved in carving. They are: knowledge of animal structure, the location of bones and joints, and the proper method of using the slicing knife and cutting board.

The direction of meat grain decides the carver's course of slicing action. All meats should be cut across the grain. Cross-grain slicing shortens the meat fibers and gives a neat slice. If the carver is not familiar with, or cannot identify the cut of meat, a safe rule is to slice parallel to the cut surface.

Carving Roast Meats.—Roast meats should be allowed to stand about 30 minutes in a warm place before being carved. This period allows for absorption of juices. The meat becomes more firm and can be sliced with greater ease and efficiency. Slicing should be done on a wooden surface because metal will turn the cutting edge of the knife. To conserve the drippings, place the meat on a carving board in a sheet pan. Then remove any string or cord which may have been used for tying the roast. Now with a sharp, long-bladed knife and a two-tined fork in hand, you are ready to carve the roast as follows.

1. Slice across the top of the roast from left to right so that carved portions are on the right side and can be easily lifted to the plate or tray.

2. Hold the roast in place by pressing the fork (which is in the left hand) firmly into the top and near the right side.

3. Carve across the grain of the meat. This cuts the long fibers and makes it seem more tender.

4. Cut thin, even slices.

Because it is important to carve a roast into uniform pieces, it is suggested that a few servings be sliced in the galley and weighed. This will help you to determine the serving size at the serving counter.

Carving and Serving Roasted Poultry

Roasted poultry should be allowed to rest 30 minutes in a warm place after removal from the oven prior to carving. This will allow a time lapse necessary for the "post-oven" rise in temperature. This rise in temperature always happens in meats or poultry after roasting in the oven. It will also allow the flesh of poultry time to firm up for better slicing.

When cooled, poultry can be carved in the galley, placed in insert pans, and served on the line. One roasted turkey, garnished and decorated, could be used on the mess line for eye appeal. Galley carving not only expedites service on the line, but greatly facilitates portion control by more careful, even slicing. To carve the turkey in the galley proceed as follows:

1. Place the cooked turkey on a cutting board.

2. Hold the wing with the left hand. Using a sharp boning knife, make a circular cut around the bone socket.

3. Twist the wing in the socket and cut the tendons at the joint. Place the wing on the cutting board.

4. Cut through the skin between the thigh and the body, pull the leg out and over to free the hip joint.

5. Use the tip of the knife to loosen the thigh meat and cut the skin along the back. Place the drumstick and thigh on the cutting board.

6. Slide the knife along one side of the keel bone from tip to the wish bone area. Cut to the shoulder joint following the curve of the wish bone. From underside of the wing socket joint continue cutting over the rib back to the beginning, the tip of the keel. The breast may be removed in one piece by inserting the knife along the rib cage and cutting along the rib bones or by inserting one's fingers into the cut along the keel bone and gently easing the breast meat outward to lift it away from the bone structure in one piece.

The second side of the turkey is carved in the same manner, then separate the drumstick and thighs, and cut the bone away from the thigh meat.

Use the slicing machine to cut the turkey breasts in nice even slices or use a sharp knife and slice by hand. Turn the chunky pieces to obtain the largest possible slices. Place the sliced turkey in a shallow insert and cover with waxed paper to prevent loss of moisture.

There are two advantages to this method of carving. It ensures portion control and makes it possible to use all other meat on the carcass in the best manner to avoid waste. That meat that is on the carcass is removed with a small knife and used for entrees such as "Turkey a la king or Creamed Turkey."

On special occasions roasted whole turkey may be carved on the serving line. This allows everyone to see and share in the festivity which a holiday bird symbolizes. This method for carving roasted whole turkey is illustrated in figure 12-1.

Be sure to store all unused portions properly. Sliced meat can be placed on a tray and covered loosely with waxed paper before placing in the refrigerator. Trimmings and other edible parts should likewise be placed in the refrigerator if they are not to be used immediately.

Carving Boneless Turkey

Machine slicing of boneless, string-tied turkey is preferred to hand slicing, if feasible.

The following method is recommended. Remove the strings and cut the boneless turkey into two equal parts lengthwise. Then place half the turkey, skin side up, against the slicing blade on the slicing machine. Cut in slices about $^1/_4$ inch thick. Place the cut slices in a shallow insert and cover with waxed paper.

If an electric slicing machine is not available, follow the same procedure using a sharp knife.

The Precooked Turkey Roll is divided in thirds, then sliced in even slices. The slices are placed in a shallow insert, covered with chicken stock, and preheated for service.

Serving Utensils

Using proper serving equipment simplifies food service and controls waste. Use a food turner for lifting such things as portions of steak, scrambled eggs, or grilled tomatoes.

1. CARVING POSITION – FIRST MOVE TURKEY COMFORTABLY CLOSE AND TURN IT ON ITS SIDE, BREAST AWAY FROM CARVER.

2. REMOVE WING – NEXT RAISE WING AND CUT IT OFF AT THE SECOND JOINT. SET WING ASIDE FOR OTHER DISHES.

3. BARE THIGH BONE – SLICE DARK MEAT OFF DRUMSTICK AND THIGH UNTIL THIGH BONE IS EXPOSED.

4. REMOVE DRUMSTICK – LIFT DRUMSTICK WITH NAPKIN AND CUT OFF AT THIGH JOINT, LEAVING THIGH ON BIRD.

5. MEAT FROM DRUMSTICK–SLICE AWAY DARK MEAT FROM DRUMSTICK.

6. CUT AWAY THIGH BONE–CUT AROUND THIGH BONE WITH KNIFE AND REMOVE FROM BIRD, AS PICTURED HERE.

7. SLICING DARK MEAT – SLICE DARK MEAT AWAY FROM TURKEY JUST ABOVE REMOVED THIGH BONE. ARRANGE NEATLY ON PLATTER.

8. BASE CUT–MAKE DEEP VERTICAL CUT IN BREAST JUST IN FRONT OF WING JOINT TO SERVE AS BASE FOR ALL BREAST SLICES.

9. BREAST SLICES–START FROM CENTER OF BREAST AND CUT TOWARD YOU, REMOVING SLICES ONE BY ONE AS SHOWN.

48.100

Figure 12-1.—Galley carving procedure for roasted turkey.

8648

For mashed potatoes or items of similar consistency, use a serving spoon or ice cream dipper. A basting spoon or other shallow spoon is appropriate for dipping sauce or gravy from a shallow pan, but use a ladle if serving from a deep well. Some foods, such as peas and boiled cabbage, should be served with a straining spoon, so that the liquid drains back into the serving pan. Serving forks are needed for some meats. Fried chicken, asparagus, broccoli, and corn on the cob are handled best with tongs.

Portions

The Commissaryman assigned to supervise the serving line has two responsibilities regarding portion control. One is to see that servings are equitable, and the other is to assure that the amounts served are not more than the individual wants.

Portion sizes of some items can be regulated on the serving line through the use of standard ladles and spoons. When you serve meat, guesswork on correct portion sizes can be eliminated by using ounce scales to check one or two slices before proceeding to cut up the entire batch. Some meat items now purchased for Navy use are precut in individual portions.

Save food, time, and confusion by asking each man if he wants a portion of the food you are serving. Not all have the same appetite. Some may not want any; some may want a medium-sized portion; and some may want a more generous serving.

Replenishing

Don't wait until you are completely out of an item before you notify the runner. Give the cooks time to get the next container ready. When you know you have about 15 servings left and you can see that there are more than that number of men in line, tell the runner so that the second container will be ready when you need it.

Empty containers should be kept off the deck and serving tables. Send them back to the galley.

SALAD BAR

Self-service salad bars (fig. 12-2 on page 194) have become very popular in the operation of the general mess. The Bureau of Medicine and Surgery authorizes placing salad bars APART from the hot food serving line, and this speeds up food service.

When you are deciding where to put the salad bar, elements such as ease of access and continuous movement of traffic should be considered. If at all possible, salad bars should be situated to permit the crew to serve themselves from the salad bar before approaching the hot food serving line. This will eliminate the stop at the salad bar enroute to the mess tables and will enable the men to eat the hot food on their mess trays while it is hot.

Coordinate salad bar menus with the salad bar space available. Overcrowding items on the salad bar detracts from the presentation of the food, hinders easy self-service, and slows the speed of service. Careful attention should be given to arrangement of the salad items to eliminate the necessity of reaching over one container of food to get to another. This is not only unsanitary but also means that particles of food are often dropped from one container to another creating, to say the least, an unappetizing array.

The master at arms can prevent this reaching-over maneuver by directing the flow of traffic around the salad bar if the bar is accessible from all sides. When the traffic passes only one side of a salad bar, arrange all containers of food side by side along the bar rather than a front-to-back arrangement.

Refrigeration of Ingredients

For proper refrigeration of ingredients, place all salad bar items in pans or in trays on a bed of ice, or on an electrically refrigerated salad bar unit. Proper drainage is essential if salad bar items are set in ice.

When the use of ice is not possible, the salad bar should be large enough to accommodate shallow pans or trays of salad bar items which are taken directly from the refrigerated spaces. Because of the high temperawure of most dining areas, easily contaminated food (salad mixtures containing meat, fish, poultry, eggs, cooked salad dressing, and mayonnaise) should be placed on the salad bar in small quantities and replenished as needed. Mayonnaise or cooked salad dressing remaining on the salad bar after serving is finished should be disposed of and NEVER mixed with other containers of these foods remaining in the refrigerated spaces.

These rules about refrigeration apply equally, of course, whether you have a separate salad bar or not.

Serving Utensils for Salads

An adequate number and the proper kinds of serving utensils for the salad bar will promote

0038 8649

good sanitary practices and keep the salad bar in neat order during self-service. Following are the most useful utensils and the foods with which they can be used:

TONGS—for relishes and green salads—carrot sticks, celery, pickles, olives, chefs salad, garden salad, and lettuce.

STRAINING SPOONS—for salads mixed with thin dressings—cole slaw, fruit salad, and cucumber and onion salad.

BASTING SPOONS—for compact salad mixtures—potato salad, ham salad, and fish salads.

DESSERT SPOONS OR TABLESPOONS—for thickened salad dressings served on the salad bar.

SMALL LADLES—for thin salad dressings.

FOOD TURNERS—for individual salads.

POLICING MESSING AREA

Sanitary practices before serving and those connected with serving operations have been discussed. It is equally important to maintain the general sanitation and neatness of the messing area during the meal and to clean up carefully when serving is finished.

The tabletops from which the men eat should always be kept clean. They should be cleaned with a sponge and sanitizing solution after every

Figure 12-2.—Self-service salad bar.

48.60

8649 8650

use, because utensils such as knives, forks, and spoons and even foods such as bread and rolls often are placed directly on the table surface. A standard stock germicide and fungicide, chlorine solution, or other acceptable sanitizing solutions are the most efficient. Sponges are preferred and are considered more economical and sanitary than rags. Change the sanitizing solution as frequently as necessary to ensure a clean solution.

Salt, pepper, and condiment containers should be washed and refilled after each meal. These containers should be arranged in uniform order on all tables. One method is to place the taller containers in the center and arrange the others in graduated order.

Messmen should be instructed to police the dining area during a meal serving period, to wipe up any spilled food immediately, and to refill any condiment containers if necessary.

8651

8835

CHAPTER 13

LANDING PARTY

In the previous chapters, you have learned what is expected of you, as a Commissaryman 3 or 2, in the preparation of a meal aboard ship or at a shore station, but this knowledge does not cover all of your duties. It is possible that you may have to go ashore with a landing party and prepare meals under emergency conditions.

In that case, before you can do any cooking, you will have some important duties to perform. You may have to lend a hand with the stretcher bearers or give medical assistance to the wounded. After this, you will have to prepare meals for exhausted and hungry men, and under battle conditions in the open air.

WATER

Safe water for drinking, cooking and washing is one of the prime concerns of those in command of landing operations.

No unit can function long without water. Personnel in even the smallest units, in the most temporary operations, must have drinkable water with them—plus the means for getting more when their supply runs out.

All water in the field should be regarded as unsafe until approved by a medical officer or his designated representative.

The choice of a water source is influenced by the quantity, quality, ease of procurement and ease of purification. A water reconnaissance should be made to find and look over available sources and to select the one that appears to be the most desirable. Some considerations of quality that should be used in the selection are freedom from:

1. Contamination by sewage, other wastes, and from pollution by chemical, biological, or radiological warfare agents.
2. Turbidity, color, and taste.
3. Excessive amounts of organic and mineral substances.

Purifying Water

Water which is from an unapproved source must be chemically treated or boiled. Receptacles used to store or carry water should be cleaned daily with boiling water. A solution of chlorinated lime (a ration of 1 part chlorinated lime to 1000 parts of water) may be used for sanitizing cans. New cans and carts in which water is to be transported should be thoroughly steamed to remove the protective coating, then super chlorinated and rinsed before being filled with water for drinking purposes.

SUPERCHLORINATION may be accomplished by the following methods:

1. One pound of grade A hypochlorite (HTH of perchloron ®) in 800 gallons or in 100 cu ft of water gives a chlorine dose of about 100 ppm (parts per million).
2. Calcium hypochlorite (chloride of lime) is less easily used and contains only about one-half as much available chlorine per unit weight of compound; therefore, 2 pounds of chloride of lime must be used in 800 gallons of water to obtain about 110 ppm chlorine.

LYSTER BAGS, which are 36-gallon canvas containers with a lid, are commonly used in the field to purify water. They usually are issued on the basis of 1 for every 100 men. When untreated water must be put in these bags, immediate treatment is necessary. A chemical kit is furnished for this purpose. It contains the following: 100 tubes, each containing $^1/_2$ gram calcium hypochlorite; 2 chlorination test kits, each with 50 orthotolidine tablets and a plastic testing tube; and 100 sodium sulphite tablets. This chemical kit will usually treat 25 bags of water. Always follow the directions that appear on the kit.

To sterilize a canteen of water use "Tablets, Water Purification, Individual, Iodine for Treating Water in Canteens, 50 tablets per bottle" and follow direction on the container. If the iodine

8652

tablets are not available, two drops of tincture of iodine can be used—waiting 30 minutes before using the water.

In very cold regions fresh water ice or snow may be melted to secure water. The ice or snow water source must be protected to prevent contamination by man or animals. When this type of water is used for drinking purposes it must be boiled or chemically treated.

REMEMBER: Winter or summer, purify water from ponds, lakes, or streams by boiling or by chemical treatment.

Storing Water

Purified water should be protected against recontamination by proper storage in a covered tank or container. If possible, seal all containers in which purified water is stored. Store water off the ground and in locations away from garbage and toilet areas.

Storage containers for purified water should be cleaned and disinfected before initial use. This can be done by washing the inside walls and the bottom with detergent, rinsing with clear water, and then rinsing with a strong chlorine solution. Use 1 teaspoonful of bleach to 1 gallon of water for the disinfection solution.

FIELD COOKING RANGES

Special cooking ranges designed for field use are usually available. These ranges consist of the M1937 field range and the field cooking outfit, small detachment. The ranges are discussed in the following paragraphs.

M1937 Field Range

The M1937 field range (fig. 13-1) is the most satisfactory equipment available for preparing meals in the field. It consists of a cabinet with necessary cooking utensils and a gasoline-burning fire unit. The range is portable and can be operated while in transit. (See fig. 13-2 for a M1937 gasoline field range outfit.)

Each range is a basic self-contained unit that may be used singly to serve up to 50 men. With additional units, the ratio of the men who can be served increases. The range can be used for boiling, roasting, frying, and griddle cooking. Also, it can be adapted as a bake oven (fig. 13-3 on page 199). Be sure you get the instruction book pertaining to the operation and maintenance of the M1937 field range.

Field Cooking Outfit, Small Detachment

The field cooking outfit is another special range designed for cooking in the field. It consists of a stove, figure 13-4 (page 200); and the necessary attachments and utensils (see figs. 13-5; 13-6; and 13-7 on pages 201, 202, and 203) required to prepare rations for 15 to 40 men. The outfit is designed primarily for out-of-door use by isolated detachments.

The Army manual, Field Cooking Outfit, Small Detachment, TM-10-7360-203-15 (Feb. 1961), contains information on the operation and maintenance of the outfit as well as a description of major components. Tools, repair parts, and supplies for use with the small detachment cooking outfit should be requisitioned by Federal stock number.

IMPROVISED COOKING UNITS

There are a variety of cooking units that may be improvised, ranging from simple grills to

Figure 13-1.—M1937 field range with utensils and fire unit.

8653

1. Aluminum cooking pot, 60-qt. capacity
2. Cabinet
3. Aluminum cooking pot, 40-qt. capacity
4. Aluminum cover for baking and roasting pan
5. Cook pot cradle
6. Kitchen dipper, 1-qt. capacity
7. Kitchen ladle, 8-oz. capacity, 15 in. long
8. Kitchen skimmer, 5 in., diameter, 15 in. long
9. Cake turner, solid blade
10. Fire unit
11. Boning knife (steel), 6-in. blade
12. Paring knife (steel), 4-in. blade (2)
13. Potato peeler (steel) (3)
14. Measuring set, 4 spoons
15. *Butcher's knife, (steel) 10 in. blade
16. Food service spoon, 21-in. long
17. Food service spoon, 15-in. long
18. Food preparation fork, 15-in. long
19. Food preparation fork, 21-in. long
20. Arm protector, short
21. Arm protector, long
22. Aluminum baking pan
23. Aluminum cooking pot cover (2)
24. Splash plate
25. Baking and roasting pan

*To be replaced by knife, steak, scimitar, 10-in. blade, pending standardization action.

48.63

Figure 13-4.—Cooking outfit, field, small detachment.

the more complex ovens. Some of these units are constructed of rubble, sheet metal, and brick, stone, or cinder block, held together by a "cement" made of mud and grass. At first, only simple units for heating water and making soup and beverages are necessary. As time and labor become more available, complex units can be constructed to permit greater variety in meals.

Open Fire Cooking and Heating Unit

In order to construct the open fire cooking and water-heating unit shown in figure 13-8 (page 204) you need the following materials:

1. Twelve brick or flat stones.
2. Four cinder or concrete blocks.
3. Half of a 55-gallon oil drum or other large container for cooking.
4. The upper half of an oil drum or a piece of sheet metal of a similar size which can be used as a shield.

On the selected site, outline a square large enough to accommodate the cooking container. Then, at the center of each of the four sides of the square, stack three bricks so that they will support the container with its edge contered on each stack. Place the pot on the stack of bricks, and bend the sheet metal to fit around the bricks, but leave about a 6-inch space between the ends of the metal (see fig. 13-8).

Finally, build a wood or coal fire at the center of the stack of bricks. Place the 6-inch opening of the shield so that it faces the wind to provide for a good draft. The shield may be moved when the wind shifts or when you wish to add fuel to the fire. Of course, safety precautions pertaining to fire prevention must be strictly observed when building any type of outdoor fire.

It is estimated that two of these units are sufficient for the preparation of food for 100 men and six are adequate to feed 500.

Crossfire Trench

If bricks, stone, or cinder blocks are not available, you may build a cross fire trench. To construct such a trench, first dig 2 trenches, each 8 feet long, 1 foot wide, and 1 foot deep, which cross at their centers. (See fig. 13-9 on page 204.) The bottom of each trench should taper up to the level of the ground toward the end, as shown in the illustration. Place scrap iron over the intersection of the trenches to make a grate. Approximately 10 pieces of scrap

8656

1 Pan, sterilizing

Figure 13-8.—Open fire cooking and heating unit.

48.68

Figure 13-9.—Crossfire trench.

iron, such as pipe, angle iron, or $^1/_2$-inch round iron, each about 2 feet long, will do.

At the intersection of the trenches, build a coal or wood fire. Then use three pieces of sheet metal, $1^1/_2$ feet long by 1 foot wide, to block off 3 of the 4 sides. Leave open the side facing the direction of the wind.

The crossfire trench can be used for both cooking and incinerating. Two of them are sufficient for preparing meals for 100 men; six are enough for the preparation of meals for 500.

A variation of this crossfire trench can also be built above ground (see fig. 13-10). For this type of trench approximately 100 bricks, 10 pieces of scrap iron for the grate, and 2 pieces of sheet metal to act as support for the grate are needed.

First lay four parallel rows of brick in a cross, so that they intersect at the center to form a firebox. Allow 1 foot of space between rows. Form the sidewalls by stacking bricks three high with mortar in between. Finally, lay the sheet metal at the intersection and place the scrap iron over the sheet metal to make the grate.

Ground Griddle

To build the ground griddle you will need:

1. Two pieces of steel plate at least 30 by 30 inches and approximately $^1/_4$ inch thick. (If only 1 piece of plate is available, it may be used instead of 2.)

2. One piece of stovepipe or several No. 10 tin cans with both ends cut out.

3. Two lengths of pipe or round iron to support the steel plate and prevent it from being overheated and buckling.

Dig a fire pit about 2 feet square and 1 foot deep. One end should slope to the level of the ground. Place lengths of pipe across the fire pit as support for the steel plate. Place 1 steel plate over the fire pit and cover it with 1 inch of sand or dirt. Then place the second plate on top of the layer of sand or dirt.

Directly behind and at the center of the deep end of the fire pit, dig a hole 6 inches square and 6 inches deep and opening into the pit to form a chimney (see fig. 13-11). Place No. 10 cans one

48.69

Figure 13-10.—Crossfire trench above ground.

48.70

Figure 13-11.—Ground griddle.

8660

on top of the other to fit over the hole in the ground and form the chimney stack. A tighter chimney may be made by cutting several inch-wide sections around the bottom edge of each can so that it fits over the rim of the connecting can. Use bricks to hold the chimney in place.

The ground griddle may also be used as a quick bread oven by covering dough placed on the steel plates with a tin can. And in the same way, it may be used as a food warmer.

It is estimated that you will need 2 ground griddles if you are to feed 100 men and 6 if you are to feed 500.

Roaster

To build a good improvised roaster, you will need:

1. One large can with a tight-fitting cover. (An institutional-size lard or shortening can is preferable.)
2. Bricks, cinder block, or stones to construct the sidewalls of the fire pit.
3. A length of steel rod, round iron, or heavy wire to be used as a spit.
4. A length of fine strong wire to tie the meat to the spit.

The improvised roaster is shown in figure 13-12. To form the brick fire pit, it is necessary only to place the bricks in a ring. Build your fire around the inside of this fire pit, allowing space in the center for the cooking container to rest on the ground.

Punch a hole for the spit on each side of the can several inches below the rim. Then wrap fine wire several times around the meat which you wish to roast, or run the wire through the center of the meat, leaving ends of wire long enough to make a strong loop. Run the spit through one hole in the can. Slip the wire loops on the roast over the spit so that the meat will hang suspended in the can. Then run the spit through the other hole.

Figure 13-12.—Improvised roaster.

Put the cover on the can and place it on the ground within the fire pit, with a weight on the cover to hold it securely. Do not put water in the can. The meat should cook in its own steam. And remember that meat cooks more quickly in this type of pressurized container. For example, a 20- to 25-pound chuck of roast beef will cook in 2 to $2^1/_2$ hours.

COOKING CONTAINERS

Before you use any containers, such as salvage oil drums, they must be cleaned, scoured, and sterilized. If there is a choice, choose containers in the following order of preference:

1. Those in which fuels, oils, and lubricants were stored.
2. Those in which chemicals and fertilizers were stored.
3. Those in which paints were stored.

When you cleanse these containers, use the following procedure:

1. Cut 55-gallon oil drums in half.
2. Wip out oil and foreign matter.
3. Fill the containers with water, add detergents, and boil the water.
4. Empty the soiled water. Use an ordinary household abrasive to scour the container thoroughly. If such an abrasive is not available, make a mixture of sand, fine gravel, and water. Remove any foreign matter deposited in crevices or under rolled rims.
5. Rinse thoroughly with hot water several times.
6. Repeat the above procedures if necessary.
7. To ensure the cleanliness and safety of a container which is to be used as a cooking vessel, you may finally BLUE it.

Bluing Emergency Containers

The purpose of bluing is to prevent rust. Aluminum and tin utensils should never be blued, because the high heat necessary to blue a utensil will melt them. To blue utensils, use the following steps.

8661

1. Wash and dry the utensil thoroughly. Place it over a wood fire that has both flames and live coals. This burns out any remaining residue and opens the tiny pores of the metal.

2. Plunge the utensil in hot water and again scour and dry it thoroughly.

3. Coat the utensil inside and out with a thin film of lard or some other cooking grease. Do not use bacon or ham grease or any other grease which contains salt that will corrode the metal.

4. Place the utensil upside down over glowing coals, being careful not to burn away the grease.

The metal will slowly turn blue as the heat does its work. The spread of color is a guide in judging the progress of the bluing. This heat treatment melts the grease into the surface, closes the pores of the metal, and gives the utensil a smooth, glazed surface that resists rust.

BATTLE RATIONS

The armed services are equipped with battle rations that are prepared so that the necessary food values are provided in a form that can be used under battle conditions. The following paragraphs discuss some of these rations.

B Operational Ration

B rations are designed for large group feedings in situations when it is impossible to provide perishable foods because of lack of refrigeration facilities but when, nevertheless, kitchen and cooking facilities are available.

The B ration may include canned meats, cereals and cereal products, canned fruits, canned milk products, canned vegetables and legumes, dehydrated fruits and vegetables, dry milk products and dried eggs.

Meal, Combat, Individual

Field ration (meal, combat, individual) was designed for use either in individual units as a meal packet, or in multiples of 3 as a complete ration. It may be eaten either hot or cold, and is packaged so that it can be carried by the individual.

Packaged by individual meal, the ration offers a variety of canned meat, fish, or poultry, canned vegetables, canned fruits, desserts, and beverages.

Emergency Coffee

Emergency coffee can be made by the kettle method with bag or without bag. Each method is discussed in the following paragraphs.

Kettle Method With Bag.—Unbleached muslin, layers of cheesecloth, or sugar sacks are suitable for making bags. NEVER use burlap sacking or other material that has been sized or otherwise treated.

The basic recipe for making coffee in a 10-gallon kettle consists of 3 pounds of coffee to $7\frac{1}{2}$ gallons of boiling water. The yield will be $7\frac{1}{2}$ gallons of coffee, 30 quarts, or 160 six-ounce portions.

The following directions should be followed to make coffee by the kettle method with a bag:

1. Place ground coffee in a cloth bag large enough to permit the circulation of water and expansion of the coffee. Allow for expansion of as much as 2 or 3 times the amount of coffee used. Fifteen pounds of coffee is the maximum per bag for best results and convenient handling.

2. Tie the bag securely near the top with strong cord or string with one end long enough to fasten to the handle of the container. This makes it possible to remove the bag easily from the hot brew.

3. Pour water (freshly drawn if possible) into a large kettle and bring it to a boil.

4. Place the coffee bag in the boiling water; tie the cord to the handle or make it secure otherwise. Reduce the heat to keep the water at just below boiling AT ALL TIMES.

5. Submerge the bag with a paddle or stick, pushing up and down gently to force water through the grounds.

6. Cover the kettle and brew the coffee 10 minutes.

7. Lift the bag and drain it into the kettle. Then remove it.

8. Finally, empty the coffee grounds; wash the bag thoroughly in plain water and place it in cold water until it is to be used again.

Emergency Method Without Bag.—In this method the basic recipe is the same as that for the kettle method with bag.

Follow these directions:

1. Pour water into a container of adequate size.

2. Heat the water to the boiling point.

3. Pour ground coffee into the boiling water and stir.

1088 8662

4. Reduce the heat to just below the boiling point.

5. Brew the coffee 10 to 12 minutes, being careful not to boil or overcook it.

6. Settle the grounds by sprinkling in a small amount of cold water. To avoid stirring up the grounds, carefully pour or ladle the coffee into another container.

HANDWASHING FACILITY

The handwashing facility illustrated in figure 13-13, has the advantage of being both simple and sanitary. In order to construct it, you will need:

1. Two No. 10 tin cans or other metal containers for water, with bails and tilt handles.

2. One length of iron rod, pipe, or wood from which to suspend the cans.

3. Six lengths of wood to form tripods, with cord or wire for typing.

First erect the tripods. Then put bails and tilt handles on the cans as shown in figure 13-13. Suspend the cans on the pole and tie them to it. Finally, place the pole on the tripods. (The area below the cans should be filled with sand or gravel so that the water from the cans will drain off and not form a mud puddle.)

Figure 13-13.—Handwashing facility.

Figure 13-14.—Washing device with soakage pit.

8663

When you are ready to use the unit, fill 1 can with soapy water and the other with a disinfecting solution consisting of 1 ounce of any ordinary household laundry bleach to 2 gallons of water. Each man using it may first pour the soapy water over his hands and then rinse them with the disinfecting solution. You should provide single-service paper towels for each person or else insist that the hands be air dried, to prevent reinfection. If you provide single towels, provide a trash can as well.

For a more permanent type of washing device see figure 13-14. You will notice that it is equipped with a grease trap and a soakage pit.

WASHING MESS GEAR AND COOKING UTENSILS

When you are in the field, it is essential to the health of all personnel that all eating and drinking utensils, as well as equipment used to prepare, cook, and serve food, be properly washed and sanitized. This duty will require close supervision. One mistake could result in many sick shipmates.

Figure 13-15 illustrates an improvised field dishwashing unit consisting of three G.I. cans in a line to form a battery. As many such batteries may be utilized as needed to handle the flow of traffic during the feeding period.

One can, which is not shown in fig. 13-15, is used for garbage and waste. The cans shown in figure 13-15 respectively contain prewash warm water and detergent; hot water with sufficient detergent so that washing is quickly and adequately accomplished; and boiling water for rinse. You can use an additional can for a second rinse. Immersion type heaters (fig. 13-16) or field burners are available for heating the water in the cans or they may be heated over fire built in a trench as shown in figure 13-15.

48.74

Figure 13-15.—Emergency dishwashing facility.

Dishwashing Procedure

Long-handled brushes should be attached to the wash cans for use in prewashing. When scraps are discarded, prewash utensils to remove food particles and grease. Then wash in hot water 110° to 130°F and detergent before immersing in the sanitizing (boiling) rinse. The utensils

48.75

Figure 13-16.—Immersion heater mounted in a corrugated can.

8664
C338

should remain in the wash and rinse water for about 30 seconds. After immersion in the boiling water, the utensils should be allowed to air dry. NEVER dry them with towels.

The prewash water should be changed as frequently as necessary to prevent carryover of grease and food particles into the rest of the system.

After the battery has been secured, the cans should be emptied, thoroughly scrubbed, flushed, and inverted to permit complete draining and drying. Mark each can for its designated use, "garbage," "prewash," "wash," and "rinse." This should aid in restricting the use of each can for the one purpose for which it is intended.

DISPOSING OF WASTE

One of your biggest jobs will be the disposal of garbage, trash, and liquid wastes from the galley. Garbage is best disposed of by burying or burning.

To bury GARBAGE, dig a trench or pit 4 or more feet deep, dump the garbage in the pit, pack it down in layers and cover the exposed layer with a few inches of dirt at the end of each day. When the pit is filled, cover it with earth and pack it down well by tamping or running over it with a crawler tractor. When you abandon a garbage site, cover it with at least 2 feet of mounded earth.

When you incinerate garbage, all excess moisture must first be removed. Then start a good fire before adding the garbage. Add it to the fire in small amounts and add fuel as needed to keep a good fire going. The unburned residue must then be buried and covered with at least 2 feet of mounded earth.

To dispose of CANS, either wash them and use them as substitutes for cooking and eating utensils, or open both ends, flatten them, and bury them with the garbage.

GLASS JARS also can sometimes be used as substitutes for eating utensils. Otherwise, break them and bury them with the garbage. Breaking them will reduce the volume and save work in digging and covering.

Bury other noncombustible wastes with the garbage, and burn the combustible wastes.

LIQUID WASTES such as grease, except any usable grease or waste fat which can be used for cooking, may be burned or buried with the garbage. Dispose of other liquid wastes in a soakage pit. This pit should be located at a minimum of 25 feet from the kitchen area.

To build a soakage pit like that shown in figure 13-17, you will need:

1. Lumber to construct a box approximately 12 inches square and 2 feet high, open at both ends.
2. Enough 1- by 4-inch lumber to construct reinforcing strips to brace the top of the box and also strips inside the box for the wire basket to rest on.
3. Two 1-inch layers of wood, with the lower layer recessed, to construct a cover to fit the top of the box.
4. A layer of wire screen, matting, gunny sacking, tar paper, or a heavy layer of newspaper to retain the earth mound above the rocks.
5. Enough rocks or rubble to fill a pit 5 feet in diameter and 5 feet deep.
6. A wire basket of approximately $^1/_2$-inch mesh hardware cloth, resting on the 1- by 4-inch wood inner strips.
7. Earth to make a mound approximately 6 inches high over the rocks.

Locate the soakage pit in well-drained ground which is suitable for good soakage, preferably sand or gravel soil. Dig a pit 5 feet in diameter and 5 feet deep. Fill the pit with rocks or rubble to within 1 foot of the ground surface. Insert the box as shown in figure 13-17. Then add enough rubble to fill the pit to the ground surface around the box. Cover the rubble with screen wire or any other material that will serve as a separator between the rubble and the earth topping, and mound dirt over the pit.

The wire basket serves to catch any large pieces of solid matter floating in the liquid. These might prevent good drainage if they were dumped into the pit. The basket may be removed and emptied as necessary.

Figure 13-17.—Soakage pit.

8665

INSECT CONTROL

Flies breed in manure and decayed matter, so keep flies out of the galley. Screen the galley if possible. Keep the food in covered or screened containers where flies can't get at it. Mosquito netting is a good material to use.

Use traps and fly swatters freely. Sticky fly paper can be made by heating castor oil (5 parts by weight) and powdered resin (8 parts) until the resin is dissolved. Don't boil this solution. Apply it to glazed paper while it is still hot or paint it on iron hoops or wire strands. Wires so painted should be cleaned and recoated every 2 or 3 days.

DDT—made especially for the Armed Forces—is the most effective means of fighting flies and other insects. Spray it around as often as necessary, but don't let it come in contact with food or utensils.

Other pests such as ants, mice, and rats can present problems which may require special controls such as those mentioned in Chapter 8, Sanitation in the General Mess.

8666

APPENDIX I

TRAINING FILM LIST

Certain training films that are directly related to the information presented in this training course are listed below under appropriate chapter numbers and titles. Unless otherwise specified, all films listed are black and white with sound, and are unclassified. For a description of these and other training films that may be of interest, see the United States Navy Film Catalog, NavWeps 10-1-777.

ABSTRACT - Developed by the Division of Curriculum and Instruction of the Milwaukee Public Schools, this curriculum guide is for instructor use in teaching the trade and industrial fundamentals of machine shop in the secondary schools. Specific objectives include development of skills necessary in the machine industry, an understanding of the importance of the metalworking industry, and an appreciation of related information. The course outline covers 20 major units, encompassing 73 sub-units, which are presented in a seven-column format. Sixty detailed prints for projects, references, a list of films and filmstrips, and a bibliography are included. (GEB)

INTRODUCTION

The curriculum guide for machine shop has been planned as an aid to the practical course which involves all levels of bench and machine work, from t The use of the curriculum guide will vary according to the equipment and tim concerned. Therefore, no sequence of instruction has been built into the gu will adapt it to make maximum use of their time and equipment.

In the presentation of this material, a concise seven-column guide has

-- Column one contains the title of the unit to be presented and the te used to cover this material. The code numbers assigned to each refe in the section entitled Bibliography, page 19.
Example: 1 - pp.101-106 lists the book GENERAL-INDUSTRIAL MACHINE S 101 to 106 as the source of information for the unit.

-- Column two lists the instructional information to be taught in this assumed that the instructor will use the listing as it best fits the which he is teaching.

-- Column three lists the suggested teaching methods that may be used the unit.

-- Column four contains a listing of films, filmstrips, charts, and par will aid in the presentation of the unit. All film numbers are pre letter F. Films are listed on page 29. Charts and pamphlets are li Supplementary Aids, page 21.

-- Column five lists drawings of various exercises and projects to be teaching the materials in the various units. The drawings themselv as the last section of this guide and are organized by drawing numb

-- Column six lists the suggested student textbook assignment to be us to the content of the unit.

-- Column seven may be used for the instructor's notes and comments--t as the unit is covered.

The purpose of this course is to prepare the high school graduate to e allied industries as an apprentice or knowledgeable production employee. S intentions, as such, to be eligible for this training. It is further inten graduation, plan to continue their education in a technical school or junio

AIMS AND OBJECTIVES

- the personality traits and abilities necessary for the machinist trade
- an awareness of accident causes and the habit of safe practices
- abilities in the use of common tools, machines, and materials as used in the metalworking s
- an understanding of the social and economic role of the metalworking industry in everyday

ize the importance of English, mathematics, and science in industrial occupations

p the practice of careful planning and good workmanship

p a program that will meet the needs of those with varying abilities, potentialities, , desires, and interests; also, to show students where these characteristics can be uccessfully in industrial and technical fields

the student in skilled processes involving the use of modern tools, machines, and materials gether with his high school academic work, will prepare him for future employment in the ndustry

p skill and accuracy in the manipulation and care of essential hand and machine tools used chinist trade

and develop the ability to gauge and measure quickly and accurately

ate independent thinking in order to strengthen the student's problem-solving ability

p an understanding of metals, their machinability, and heat treatment

p an understanding of related information, such as blueprint drawing and reading, foundry , patternmaking, shop mathematics, on-the-job training, apprenticeship training, unions, s, employee and employer attitudes and responsibilities, etc.

DESCRIPTION OF THE MACHINE SHOP COURS

This machine shop course has been geared toward the vocational tr entrance into the field of metalworking and other allied industries, e production worker with on-the-job training.

The course, as taught, will require a minimum time of one period eleventh and twelfth grades, except Boys' Technical High School which periods a day for seven semesters from the ninth through twlefth grade offered for the course--per period, per semester.

The prerequisites for taking the course are an indication of abi through aptitude tests and the Kuder Interest Inventory, plus the rec staff. Students should be between the ages of fourteen and nineteen. class enrollment is twenty students.

DESCRIPTION OF THE MACHINE SHOP COURSE

ne shop course has been geared toward the vocational training of young people for he field of metalworking and other allied industries, either as an apprentice or er with on-the-job training.

, as taught, will require a minimum time of one period a day for four semesters in the elfth grades, except Boys' Technical High School which schedules machine shop two or seven semesters from the ninth through twlefth grades. One-half credit will be course--per period, per semester.

uisites for taking the course are an indication of ability and interest as expressed e tests and the Kuder Interest Inventory, plus the recommendation of the guidance s should be between the ages of fourteen and nineteen. The recommended individual t is twenty students.

ABSTRACT - Developed by the Division of Curriculum and Instruction of the Milwaukee Public Schools, this curriculum guide is for instructor use in teaching the vocational aspects of power and transportation and in teaching the principles of automotive engine tune-up in the secondary schools. The material is designed to cover a period of four school years and is broken into four basic parts. The first part is an introduction to power and transportation, the second is a more in-depth study, the third includes the theory and testing of systems, and the fourth part places emphasis on actual diagnosing and solving automobile engine problems with the use of test instruments. A 5-column format is used to present the material to best advantage. Objectives include the teaching of skills in the use of tools and equipment, development of an awareness of the industry, and acquaintance with products in the power and transportation field. An extensive list of supplementary aids, and a bibliography are included. (GEB)

ACKNOWLEDGMENT

Appreciation is expressed to the Advisory Committee for Power and Transportation whose suggestions and contributions helped to make the writing of this guide possible. The actual organizing, compiling, and writing of the material was done by Howard Davenport and Ronald Disch.

Wilbert C. Bohnsack, Coordinator
Industrial Education

Frisby D. Smith, Executive Director
Secondary Curriculum and Instruction

Dwight Teel, Assistant Superintendent
Division of Curriculum and Instruction

Harold S. Vincent, Superintendent of Schools

AIMS AND OBJECTIVES

-- To develop an awareness of the industrial complexes related t
tion field

-- To train the student to be a responsible working member of an
laboratory or industrial activities

-- To acquire skills in using the tools and equipment of the pow
field

-- To present the student with vocational information and guidan
and transportation

-- To become acquainted with the various products of the power

-- To become acquainted with various methods of manufacturing i
transportation industry

-- To become aware of the technological advancements in the pow
field

AIMS AND OBJECTIVES

lop an awareness of the industrial complexes related to the power and transporta-
eld

n the student to be a responsible working member of any group involved in
ory or industrial activities

ire skills in using the tools and equipment of the power and transportation

ent the student with vocational information and guidance in the area of power
nsportation

me acquainted with the various products of the power and transportation field

me acquainted with various methods of manufacturing in the power and
ortation industry

me aware of the technological advancements in the power and transportation

INTRODUCTION

This curriculum guide for power and transportation has that a varied program can be offered in all of the area high guide may be enlarged upon if shop facilities permit. Shop aids will determine depth of content and the amount of time therefore, this guide does not include a suggested timetable correlate classroom theory and practical shop application in possible, related shop skills should be developed. Instruct administered at the conclusion of the various units of work teacher.

In presenting the material, a concise, five-column form

-- The first column lists the areas emphasized in prese

-- Column two lists the exercises and activities by whi emphasis listed in the preceding column are presente

-- References to textbooks and jobs are made in the thi letter preceding the indicated pages or job number r letter preceding the book title as listed in the bib

-- Films, filmstrips, booklets, etc., are listed by cod column four. Titles will be found in the section en Aids on page 66.

-- In the last column, space is provided for the instru of lectures and demonstrations, time spent on variou instruction, and other information for his personal

INTRODUCTION

culum guide for power and transportation has been planned in such a way
rogram can be offered in all of the area high schools. Sections of this
larged upon if shop facilities permit. Shop facilities and supplementary
mine depth of content and the amount of time spent in any one area;
guide does not include a suggested timetable. It is not feasible to
room theory and practical shop application in all areas. However, when
ed shop skills should be developed. Instructor-made tests may be
the conclusion of the various units of work or at the discretion of the

ing the material, a concise, five-column format has been used:

POWER AND TRANSPORTATION 1 AN

This introductory course deals with the source, genera utilization of power as developed by the internal combustio aircraft, automotive, marine, and small engines. In the fi student should be instructed primarily on engines and engi semester work is centered around the small gasoline engine. practical experience in disassembly, cleaning, and servicin auxiliary systems. In Power and Transportation 2, the stud experience on a complete engine.

The experiences of the first two semesters are designe appreciation of the value, service, and place of the intern nation's economy.

8947

8920

POWER AND TRANSPORTATION 1 AND 2

ductory course deals with the source, generation, transmission, and
power as developed by the internal combustion engine. The course includes
otive, marine, and small engines. In the first semester of work the
be instructed primarily on engines and engine systems. The second
s centered around the small gasoline engine. In Power and Transportation 1,
ience in disassembly, cleaning, and servicing is restricted to the
ns. In Power and Transportation 2, the student is exposed to practical
complete engine.

ences of the first two semesters are designed to help the student gain an
the value, service, and place of the internal combustion engine in our
y.

ABSTRACT - Designed to present the basic operations using handtools required for the performance of a wide variety of jobs, this book was developed by the Department of Navy. The text is divided into two parts: (1) descriptions, illustrations, general uses, and approved maintenance procedures for handtools and portable power tools, and (2) a description of the way in which the tools are used in specific operations. Topics are: (1) Common handtools, (2) Common power tools, (3) Fastening devices, (4) Measuring, (5) Laying out, (6) Testing, checking, and setting, (7) Woodcutting operations, (8) Grinding and filing operations, (9) Metal cutting operations, and (10) Miscellaneous skills. A training film list, tables of information, and electrical safety precautions are appended and a tool and operations index are provided. (GB)

NAVY TRAINING COURSE NAVPERS 10085-A

PREFACE

Use of handtools and of portable power tools is basic to almost every rating in the Navy. This book is designed to present, in a concise form, the basic operations required for the performance of a wide variety of jobs. Few jobs consist of a single operation; but when the separate operations are properly learned, it will be a fairly simple matter to combine separate operations so as to meet the requirements of specific jobs.

For example, such jobs as replacing a wooden shelf, crating a piece of machinery, or shoring up a damaged bulkhead, require the knowledge of several operations—measuring, job layout, sawing to size, planing, and finishing. The Navy man who has learned to do the individual operations should have no trouble with the various combinations of operations necessary to perform the overall job.

The individual operations described in this text cover the following broad areas: measuring skills; layout skills, testing, checking, and setting; woodcutting skills; grinding and filing; and metal cutting skills.

A description of how this text may be used to the best advantage is included immediately after this preface. Everyone should read the description, and should familiarize himself with the index of operations, the tool index, and the appendixes, at the back of this book. The indexes simplify the problem of locating the information concerning a specific work operation, or a special tool. The appendixes include tables of useful information that may be helpful in doing specific work operations.

This manual has been prepared by the Navy Training Publications Center, for the Bureau of Naval Personnel. Special assistance has been rendered by various Navy personnel specially cognizant of the handtools and portable power tools used, and the work operations in which they are chiefly employed.

HOW TO USE THIS BOOK

This current revision of Basic Handtools brings the information in the original text (Basic Hand Tool Skills) up to date with current practice, eliminating some material now adequately covered in other Navy training manuals, and expanding the text, especially in the areas of grinding and cutting skills.

The present text is divided into two parts: (1) a description of the tools themselves, and (2) a description of the way in which the tools are used in specific operations.

In part I, therefore, you will find descriptions, illustrations, general uses, and approved maintenance procedures for those handtools and portable power tools commonly used in the Navy. It provides all the information necessary to enable you to identify tools and fastening devices by their correct names; to understand the specific purposes and uses of each tool; and to learn the care and maintenance required to keep the tools in proper operating condition.

However, the real need of Navy men is to learn the use of the tools in performing the duties listed in the qualifications of their respective ratings. Part I of this text provides the required basic information concerning the tools; but part II teaches the reader how to use these tools in practical application. It emphasizes the operations performed in doing typical Navy jobs. After these operations have been learned, there must be sufficient practice to develop that skill in performance which is certainly as necessary as the knowledge of how the operations should be performed.

The following suggestions are given both for the performing of a specific job, and for the developing of specific skills even when no specific job is assigned:

1. When you are assigned a job that involves the use of handtools, use the operations index of this training manual to locate the major operation in part II.
2. Study the text material relating to the operation, and study the illustrations.
3. If the operation requires the use of any tool which you have not previously studied, use the tool index to locate the tool in part I. Study the description, illustration, general uses, and maintenance procedures for the tool.
4. If possible, practice each operation for a few times, before starting the job.
5. Check the text again, to ensure that you have a correct understanding of the order of the operations.
6. Perform the job.
7. If no specific job is involved, have an experienced man check your performance after you have practiced each operation.
8. Keep track of your proficiencies until you have successfully covered all operations involving the use of handtools and portable power tools.

9101

Always keep in mind that a knowledge of the tools and their uses is a fundamental requirement, the preliminary step in mastering basic hand-tool skills. The next step is careful practice, until you have mastered the various skills involved. The end result must be that you become capable of performing required operations, and of meeting the standards established in your rating qualifications. To accomplish this final result, you must first STUDY the tools and skills; then you must PRACTICE the skills; and finally you must DEMONSTRATE the skills.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

GOIB 9104

Figure 1-1-2.—Variations of the ball-peen hammer.

Simple as the hammer is, there is a right and wrong way of using it. (See fig. 1-1-4.) The most common fault is holding the handle too close to the head. This is known as choking the hammer, and reduces the force of the blow. It also makes it harder to hold the head in an upright position. Except for light blows, hold the handle close to the end to increase the lever arm and produce a more effective blow. Try to hit the object with the full face of the hammer. Hold the hammer at such an angle that the face of the hammer and the surface of the object being hit will be parallel. This distributes the force of the blow over the full face and prevents damage to both the surface being struck and the face of the hammer.

Figure 1-1-4.—Right and wrong way to use a ball-peen hammer.

Figure 1-1-3.—Soft face hammers.

CARPENTER'S HAMMER

The carpenter's hammer is either a curved-claw or straight-claw hammer. The face may be either a bell-faced or plain faced. (See fig. 1-1-5.) The carpenter's hammer generally used in the Navy is the curved claw, bell-faced hammer. The hammers may have either a steel or wooden handle; however the wooden handle is

most common. The primary use of the carpenter's hammer is to drive or draw (pull) nails.

29.5A
Figure 1-1-5.—Bell-faced and plain faced claw hammers.

MALLETS AND SLEDGES

The mallet is a short-handled tool used to drive wooden-handled chisels, gouges, wooden pins, or small stakes. It is also used to form or shape sheet metal where hard-faced hammers would mar or injure the finished work. For example a rubber-faced mallet is used for knocking out dents in an automobile. Its heads are made from a soft material, usually wood, rawhide, or rubber. It is cylindrically shaped with two flat driving faces that are reinforced with iron bands. (See fig. 1-1-6.) The mallet and hammer are used in the same way. Never use a mallet to drive nails, screws, or any object that may cause damage to the face.

The sledge is a steel headed, heavy duty driving tool that can be used for a number of purposes. Short-handled sledges are used to drive bolts, driftpins, and large nails, and to strike cold chisels and small hand rock drills. Long-handled sledges are used to break rock and concrete, to drive spikes, bolts, or stakes, and to strike rock drills and chisels.

The head of a sledge is generally made of a high carbon steel and may weigh from 6 to 16 lb. The shape of the head will vary according to the job for which the sledge is designed.

44.2
Figure 1-1-6.—Steel reinforced wooden mallet.

MAINTENANCE OF STRIKING TOOLS

Hammers, sledges, or mallets should be cleaned and repaired if necessary before they are stored. Hammer and sledge faces should be free from oil or other material that would cause the tool to glance off nails, spikes, or stakes. The hammer heads should be dressed to remove any battered edges. Inspect the handles of striking tools and make sure they are secure to the head and do not have any cracks or splinters.

Never leave a wooden or rawhide mallet in the sun, as it will dry out and may cause the head to crack. A light film of oil should be left on the mallet to maintain a little moisture in the head.

Replace Hammer Handle

When a hammer handle becomes damaged or loose in the hammerhead, it should be replaced before the hammer is used. A serious injury to yourself or a shipmate can result from using a hammer that has a bad handle.

The first step in replacing a hammer handle is to remove the old handle. If the handle is tight in the head, saw off the old handle next to the head. (See fig. 1-1-7.) Do not saw the handle off so close to the head that the saw teeth will touch the head while sawing, thus damaging the set of the saw. A hacksaw may also be used for this purpose.

Place the head of the hammer in a vise and drill a hole in the part of the handle that remains in the head. Remove the rest of the handle by driving it from the head.

The new handle should fit snugly in the hammerhead. Use a wood rasp to shape the handle to fit the head. Check the fit of the head on the handle occasionally, and make sure you do not remove too much material from the new handle. After the correct fit has been attained, seat the

11.178.1B

Figure 1-1-7.—Removing old hammer handle.

handle firmly in the head by hitting the end of the handle with a mallet. (See fig. 1-1-8.) Saw off the projecting portion of the handle, and use a small wood chisel to cut slits for the wedges if wooden wedges are used. Either wooden or metal wedges may be utilized. When the wedges have been driven in the handle, grind the end of the handle even with the head.

COMMON MISUSES

Never strike a hardened steel surface with a hammer. This misuse is a serious safety hazard. Small pieces of sharp, hardened steel may break from the hammer and also from the hardened steel. Besides causing damage to the work and/or the hammer, a serious eye injury may result.

Do not use a hammer handle for bumping parts in assembly, and never use as a pry bar. Such abuses will cause the handle to split, and a split handle can produce bad cuts or pinches. When a handle splits or cracks, do not try to repair it by binding with string or wire. REPLACE IT.

WRENCHES

A wrench is a basic tool that is used to exert a twisting force on bolt heads, nuts, and studs. The special wrenches designed to do certain jobs are in most cases variations of the basic wrenches that will be described in this section.

Some ratings will naturally have more use for wrenches in doing their jobs than other ratings; however, practically all ratings, including clerical, will have occasion, from time to time, to use wrenches. It is necessary, therefore, that all hands have a basic understanding of the description and uses of wrenches.

The best wrenches are made of CHROME-VANADIUM STEEL. Wrenches made of this material are light in weight and almost unbreakable. This is an expensive material, however, so the most common wrenches found in the Navy are made of forged carbon steel or molybdenum steel. These latter materials make good wrenches, but they are generally built a little heavier and bulkier in order to achieve the same degree of strength.

The size of any wrench used on bolt-heads or nuts is determined by the size of the opening between the jaws of the wrench. The opening of a wrench is manufacturered slightly larger than the bolt head or nut that it is designed to fit. Hex-nuts (six-sided) and heads are measured across opposite flats. A wrench that is designed to fit a 3/8-inch nut or bolt usually has a clearance of from 5 to 8 thousandths of an inch. This clearance allows the wrench to slide on and off the nut or bolt with a minimum of "play." If the wrench is too large, the points of the nut or bolt head will be rounded and destroyed.

11.178.1C

Figure 1-1-8.—Seating hammer handle in head.

OPEN-END WRENCHES

Solid, nonadjustable wrenches with openings in one or both ends are called open-end wrenches. (See fig. 1-1-9.) Usually they come in sets of from 6 to 10 wrenches ranging from 5/16 to 1 inch. Wrenches with small openings are usually shorter than wrenches with large openings. This proportions the lever advantage of the wrench to the bolt or stud and helps prevent wrench breakage or damage to the bolt or stud.

Open-end wrenches may have their jaws parallel to the handle or at angles anywhere up to 90 degrees. The average is about 15 degrees. Handles are usually straight, but may be curved. Those with curved handles are called S-wrenches. Other open-end wrenches may have offset handles, to reach nut or bolt heads that are sunk below the surface.

One of the wrenches shown in figure 1-1-9 has jaws that are set on a 15-degree angle to the handle and one that is on a 90-degree angle. The reason why the jaws are placed at an angle becomes obvious when you have to work in close places.

There are special open-end wrenches, called TAPPET WRENCHES, which are very thin and have extra long handles. They are used to adjust the tappets of engine valves. These tappet wrenches are of light construction and the jaws of the wrench will spread easily, therefore, they should never be used for any purpose other than that for which they are intended.

Figure 1-1-9.—Open-end wrenches. 1.16.1

BOX-END WRENCHES

Box-end wrenches have either 6, 8, 12, or 16 points inside the head. (See fig. 1-1-10.) The number of points determine the strength of the head. Six and eight point wrenches are used for heavy duty, 12 for medium duty and 16 for light duty work. The 12 point box-end wrench is the most common and can be used with a minimum swing of 30 degrees.

There is little chance of the box-end wrench slipping off the nut when the proper size wrench is used. Because the sides of the "box" opening are so thin, this wrench is suitable for turning nuts which are hard to get at with an open-end wrench. The offset box-end wrench (fig. 1-1-11) is especially useful in this respect.

There is one disadvantage to using box-end wrenches. You lose time if you use it to turn the nut all the way off the bolt once it is broken loose. You must lift the wrench completely off the nut after each pull, then place it back on in

1.16.2
Figure 1-1-10.—12-point box-end wrench.

1.16.3
Figure 1-1-11.—Box-end and combination wrenches.

another position. The only time this procedure is not necessary is when there is room to spin the wrench in a complete circle.

After a tight nut is broken loose, it can be unscrewed much more quickly with an open-end wrench than with a box wrench. This is where a combination box-open end wrench comes in handy. (See fig. 1-1-11.) You can use the box-end for breaking nuts loose or for snugging them down, and the open end for faster turning.

For heavy-duty work, there are long-handled, single box-end wrenches. They are made only in the larger sizes, and you can apply all the pressure you need.

The correct use of open-end and box-end wrenches can be summed up in a few simple rules, most important of which is to be sure that the wrench properly fits the nut or bolt head.

When you have to pull hard on the wrench, as in loosening a tight nut, make sure the wrench is seated squarely on the flats of the nut.

PULL on the wrench—DO NOT PUSH. Pushing a wrench is a good way to skin your knuckles if the wrench slips or the nut breaks loose unexpectedly. If it is impossible to pull the wrench, and you must push, do it with the palm of your hand and hold your palm open.

Only actual practice will tell you if you are using the right amount of force on the wrench. The best way to tighten a nut is to turn it until the wrench has a firm, solid "feel." This will turn the nut to proper tightness without stripping the threads or twisting off the bolt. This "feel" is developed by experience alone. Practice until you have mastered the "feel."

Hammering on wrenches is strictly taboo—with one exception. There is a special type of box wrench, made strong and heavy so that you can hammer on it. The handle is short and has a steel pad on which the hammer blows are struck. This wrench is known as a "slugging" or "striking" wrench. Never place a piece of pipe over the handle of a wrench to increase leverage. This practice will damage the wrench and/or the nut or bolt that you are trying to tighten or loosen.

SOCKET WRENCHES

Early models of sockets were square or hexagonal sockets integral with a T or offset handle. (See fig. 1-1-12.) This type wrench is still in use but is generally made in large sizes. Socket sets presently used contain an assortment of individual sockets made to fit different handles. There are several types of handles and extensions (fig. 1-1-13), such as the T-handle, ratchet handle, screwdriver grip handle, and a "speed" handle. These handles and sockets can be assembled in combinations that will do most any job quickly and easily.

Figure 1-1-12.—Socket wrenches.[29.7A]

The nut opening of the socket is usually 8 or 12 points similar to the box-end wrench. Six-point sockets are still used for extra heavy-duty sockets or for large sockets. The end of the socket opposite the nut opening (fig. 1-1-14) has a square hole into which the handle fits. The size of the socket set is designated by the size of the square on the drive end of the handle. A spring loaded ball on the handle snaps into a groove in the socket to prevent it from falling off.

Sockets are usually furnished in sets for a range of different size nuts. The standard sizes are 3/8-, 7/16-, 1/2- and 3/4-inch drive. The larger sizes have sockets that are designed for heavier work and larger size nuts. For extra-heavy-duty jobs larger size sets are available.

Sockets with thin walls may be obtained for use in extremely close quarters, but their use is not recommended for general work.

A universal joint (fig. 1-1-15) frequently comes in handy when working on nuts in places where a straight wrench cannot be used. The universal is placed between the handle and the socket and enables you to work the wrench handle at an angle to the socket. This comes in very handy when working in close places.

Large socket wrench sets also contain a set of extra deep sockets, generally 3 to 5 inches long. These sockets are especially useful when removing or replacing spark plugs or when removing or replacing nuts that are a long way down on the bolt.

Torque Wrench

An accessory for the socket wrench is a handle for the sockets that measures the amount of pull you exert on the wrench. This is called a "torque wrench." (See fig. 1-1-16.) This wrench is not supplied with the regular socket set but may be purchased separately.

Most modern-day machinery is assembled with close clearances, therefore it is important that the correct amount of pressure be put on the nuts and bolts that hold it together. Manufacturers' manuals generally specify the amount of torque that is to be applied to the nuts. A torque wrench enables you to tell when these specifications have been met.

The accuracy of torque-measuring depends a lot on how accurately the threads are cut, and the cleanliness of the threads. Make sure you inspect and lubricate threads in order to get the most accurate torque reading possible.

ADJUSTABLE WRENCHES

A handy all-round wrench that is generally included in every toolbox is the adjustable open-end wrench. (See fig. 1-1-17.) This wrench is not intended to take the place of the regular solid open-end wrench for steady, hard service. One jaw of the adjustable open-end wrench is fixed; the other jaw is moved along a slide by a screw adjustment. The angle between the jaw opening and the handle is 22 1/2 degrees. The wrenches are available in varying sizes ranging from 4 to 18 inches in length.

Figure 1-1-13.—Socket wrench ratchets, handles and extensions.[44.3]

Figure 1-1-14.—12-point sockets.[44.4]

When using the adjustable end wrench be sure to pull on the side of the handle attached to the fixed jaw. Make sure the jaws of the wrench are adjusted to closely fit the nut. A loose fit on the nut will tend to round off the corners of the nut.

When rotating round work an adjustable pipe wrench (Stillson) may be used. (See fig. 1-1-18.) The movable jaw on a pipe wrench is pivoted to permit a gripping action on the work. These tools must be used with discretion, as the jaws are serrated and always make marks on the work. The jaws should be adjusted so the bite on the work will be taken at about the center of the jaws.

A different type pipe wrench, used mostly on large sizes of pipe, is the chain pipe wrench. (See fig. 1-1-19.) This tool works in one direction only, but can be backed partly around the

9111

Figure 1-1-15.—Universal joint for sockets. 44.5

Figure 1-1-16.—Torque wrenches for use with sockets. 5.9(44)

Figure 1-1-17.—Adjustable open-end wrench. 29.7(44)

Figure 1-1-18.—Adjustable pipe wrench. 44.6

Figure 1-1-19.—Chain pipe wrench. 44.7

work and a fresh hold taken without freeing the chain. To reverse the operation the grip is taken on the opposite side of the head. The head is double ended and can be reversed when the teeth on one end are worn out.

The strap type pipe wrench is sometimes used for turning pipe. It is similar to the chain pipe wrench but uses a heavy web strap in place of the chain. This wrench is used where you do not want to mar the surface of the work such as fittings and pipe that are chromium plated.

The old fashioned monkey wrench (fig. 1-1-20) is still used a little by Navy personnel. It works well on large square nuts, but is too bulky for most small jobs. The jaws make an angle of 90 degrees with the handle, and should always point in the direction of pull. In some models of the monkey wrench the jaws are adjusted by turning a knurled nut, in others the handle is turned.

SPANNER WRENCHES

Spanner wrenches are wrenches that are used on special nuts. They are not generally included in a toolkit but are kept in a central

1.17.5

Figure 1-1-20.—Monkey wrench.

tool crib. They can be drawn out for use when the need arises. There are a number of types of spanner wrenches. The HOOK SPANNER (fig. 1-1-21) works on a round nut which has a series of notches cut in its outer surface. The hook (lug) is placed in one of these notches and the handle turned to loosen or tighten the nut. Fig 1-1-22 shows an adjustable type of spanner. The hook end of the wrench is hinged so that it will fit various sizes of nuts.

1.17.3

Figure 1-1-21.—Hook Spanner wrench.

44.8

Figure 1-1-22.—Adjustable hook spanner wrench.

HEX-WRENCHES (ALLEN)

In some places it is desirable to use recessed heads on setscrews and capscrews. This type screw is used extensively on office machines and in machine shops.

Recessed head screws usually have a hex-shaped (six-sided) recess. To remove or tighten this type screw requires a special wrench that will fit in the recess. This wrench is called an Allen-type wrench. Allen-type wrenches are made from hexagonal L-shaped bars of tool steel. They range in size from 1/8 to 3/4 inch. When using the Allen-type wrench make sure you use the correct size to prevent rounding or spreading the head of the screw.

NONSPARKING WRENCHES

Nonsparking wrenches are wrenches that will not cause sparks to be generated when working with steel nuts and bolts. They are generally made from a copper alloy (bronze). However, they may be made from other nonsparking materials.

Nonsparking wrenches must be used in areas where flammable materials are present. These tools are used extensively when working around gasoline-carrying vehicles and when working around aircraft.

RULES FOR WRENCHES

There are a few basic rules that you should keep in mind when using wrenches. They are:

1. Always use a wrench that fits the nut properly.
2. Keep wrenches clean and free from oil. Otherwise they may slip, resulting in possible serious injury to you or damage to the work.
3. Do not increase the leverage of a wrench by placing a pipe over the handle. Increased leverage may damage the wrench or the work.
4. Provide some sort of kit or case for all wrenches. Return them to it at the completion of each job. This saves time and trouble and facilitates selection of tools for the next job. Most important, it eliminates the possibility of leaving them where they can cause injury or damage to men or equipment.
5. Determine which way a nut should be turned before trying to loosen it. Most nuts are turned counterclockwise for removal. This may seem obvious, but even experienced men have been observed straining at the wrench in the tightening direction when they wanted to loosen it.
6. Learn to select your wrenches to fit the type of work you are doing. If you are not familiar with these wrenches, make arrangements to visit a shop that has most of them and get acquainted.

METAL CUTTING TOOLS

There are many types of metal cutting tools used by skilled mechanics of all ratings. As you

become better acquainted with your rating, you will probably discover many tools that you use for cutting metal that are not described in this text. In this text, only the basic hand metal cutting tools will be considered. No matter how technical your work is you will find that certain jobs are done better and quicker with the basic handtool. The "how to do" certain jobs will be explained in a later section of this text.

SNIPS

One of the handiest tools for cutting light sheet metal is the hand snip (tin snips). The STRAIGHT HAND SNIPS shown in fig. 1-1-23 have blades that are straight and cutting edges that are sharpened to an 85-degree angle. Snips like this can be obtained in different sizes ranging from the small 6-inch snip to the large 14-inch. They are designed to cut sheet metal up to one-sixteenth inch in thickness. They will also work on slightly heavier gages of soft metals such as aluminum alloys.

Snips will not remove any metal when a cut is made. There is danger, though, of causing minute metal fractures along the edges of the metal during the shearing process. For this reason it is better not to cut exactly on the layout line in an attempt to avoid too much finish work.

Cutting extremely heavy gage metal always presents an opportunity to spring the blades. Once the blades are sprung, hand snips are useless. Use the rear portion of the blades only, when cutting heavy material. This not only avoids the possibility of springing the blades but also gives you greater cutting leverage.

44.9

Figure 1-1-23.—Straight hand snips.

Never use tin snips to cut hardened steel wire or other similar objects. Such use will dent or nick the cutting edges of the blades.

It is hard to cut circles or small arcs with straight snips. There are snips expecially designed for circular cutting. They are called CIRCLE SNIPS, HAWKS-BILL SNIPS, TROJAN SNIPS, and AVIATION SNIPS. (See fig. 1-1-24.) Use these snips in the same manner as you would use straight snips and observe the same precautions. Like straight snips they come in many different sizes.

Many snips have small serrations (notches) on the cutting edges of the blades. This tends to

CIRCLE SNIPS

HAWKS-BILL SNIPS

TROJAN SNIPS

AVIATION SNIPS

44.10

Figure 1-1-24.—Snips for cutting circles and arcs.

prevent them from slipping backwards when a cut is being made. Although this feature does make the actual cutting much easier, it mars the edges of the metal slightly. You can remove these small cutting marks if you allow proper clearance for dressing the metal to size. There are many other types of hand snips used for special jobs. The snips discussed here can be used for almost any common type of work.

Learn to use snips properly. They should always be oiled and adjusted to permit ease of cutting and to produce a surface that is free from burrs. If the blades bind, or if they are too far apart, the snips should be adjusted.

Never use snips as screwdrivers, hammers, or pry bars. They break easily. Do not attempt to cut heavier materials than the snips are designed for. Never toss snips in a toolbox where the cutting edges can come into contact with other tools. This dulls the cutting edges and may even break the blades. When snips are not in use, hang them on hooks or lay them on an uncrowded shelf or bench.

HACKSAWS

Hacksaws are used to cut metal that is too heavy for snips. Such things as bolts and metal bar stock can be cut with hacksaws. There are two parts to a hacksaw; the frame and the blade. Common hacksaws have either an adjustable or solid frame. (See fig.1-1-25.) Since hacksaw blades are made in different lengths, most hacksaws found in the Navy are of the adjustable frame type. Adjustable frames can be made to hold blades from 8 to 16 inches long, while those with solid frames take only the length blade for which they are made. This length is the distance between the two pins that hold the blade in place.

Figure 1-1-25.—Hacksaws. 1.19(44)

Hacksaw blades are made of high-grade tool steel, hardened and tempered. There are two types, the all-hard and the flexible. All-hard blades are hardened throughout, whereas only the teeth of the flexible blades are hardened. Hacksaw blades are about one-half inch wide, have from 14 to 32 teeth per inch, and are from 8 to 16 inches long. The blades have a hole at each end which hooks to a pin in the frame. All hacksaw frames which hold the blades either parallel or at right angles to the frame are provided with a wingnut or screw to permit tightening or removing the blade.

The SET in a saw refers to how much the teeth are pushed out in opposite directions from the sides of the blade. The four different kinds of set are ALTERNATE set, DOUBLE ALTERNATE set, RAKER set, and WAVE set. Three of these are shown in figure 1-1-26.

Figure 1-1-26.—"Set" of hacksaw blade teeth. 28.40(44)

The teeth in the alternate set are staggered, one to the left and one to the right throughout the length of the blade. On the double alternate set blade, two adjoining teeth are staggered to the right, two to the left, and so on. On the raker set blade, every third tooth remains straight and the other two are set alternately. On the wave (undulated) set blade, short sections of teeth are bent in opposite directions.

The main danger in using hacksaws is injury to your hand if the blade breaks. The blade will break if too much pressure is applied, when the saw is twisted, or when the cutting speed is too fast. If the work is not tight in the vise, it will sometimes slip, twisting the blade enough to break it.

Selecting the proper blade for certain jobs and more on how to use the hacksaw can be found in part II, section 6 of this text.

282-344 O - 67 - 2

CHISELS

Chisels are tools that can be used for chipping or cutting metal. They are made from a good grade tool steel with a hardened cutting edge and a beveled head. They will cut any metal that is softer than materials of which they are made. When it is skillfully used, the chisel can be made to do most any job that a milling machine can do, although it is perhaps less accurate and requires greater time and energy.

Usually the bar stock from which a chisel is forged is octagonal (eight-sided). Cold chisels are classified according to the shape of their points, and the width of the cutting edge denotes their size. The most common shapes of chisels are flat (cold chisel), cape, round nose, and diamond point. (See fig. 1-1-27.)

Figure 1-1-27.—Metal-working chisels. 29.9(44)

The type chisel most commonly used is the flat cold chisel, which serves to cut rivets, split nuts, chip castings, and cut thin metal sheets. Also used for special jobs is the cape chisel for cutting keyways, narrow grooves and square corners, the round-nose chisel for semicircular grooves and for chipping inside corners with a fillet, and the diamond-point for cutting V-grooves and sharp corners.

As with other tools there is a correct technique for using a chisel. Select a chisel that is large enough for the job. Be sure to use a hammer that matches the chisel; that is, the larger the chisel, the heavier the hammer. A heavy chisel will absorb the blows of a light hammer and will do virtually no cutting.

As a general rule, hold the chisel in the left hand with the thumb and first finger about 1 inch from the top. It should be held steadily but not tightly. The finger muscles should be relaxed, so if the hammer strikes the hand it will slide down the tool and lessen the effect of the blow. Keep the eyes on the cutting edge of the chisel, not on the head, and swing the hammer in the same plane as the body of the chisel. If you have a lot of chiseling to do, slide a piece of rubber hose over the chisel. This will lessen the shock to your hand.

When using a chisel for chipping, always wear goggles to protect your eyes. If other men are working close by, see that they are protected from flying chips by erecting a screen or shield to contain the chips. Remember that the time to take these precautions is before you start the job.

FILES

A toolkit for nearly every rating in the Navy is not complete unless it contains an assortment of files. There are a number of different types of files in common use, and each type may range in length from 3 to 18 inches. They are graded according to the degree of fineness, and according to whether they are single- or double-cut.

The length of a file is the distance from the tip to the heel, and does not include the tang. (See fig. 1-1-28.)

Figure 1-1-28.—File nomenclature. 1.20.1

In selecting a file for a job, the shape of the finished work must be considered. Files come in different shapes, both outline and cross sectional shape. Some of the cross sectional shapes are shown in fig. 1-1-29.

Figure 1-1-29.—Cross-sectional shapes of files. 1.20.2

9116

TRIANGULAR files are tapered (longitudinally) on all three sides. They are used to file acute internal angles, and to clear out square corners. Special triangular files are used to file saw teeth.

MILL files are tapered in both width and thickness. One edge has no teeth and is known as a SAFE EDGE. Mill files are used for smoothing lathe work, drawfiling, and other fine, precision work. Mill files are always single-cut.

FLAT files are general-purpose files and may be either single- or double-cut. They are tapered in width and thickness. HARD files, not shown, are somewhat thicker than flat files. They taper slightly in thickness, but their edges are parallel.

SQUARE files are tapered on all four sides and are used to enlarge rectangular-shaped holes and slots. ROUND files serve the same purpose for round openings. Small round files are often called "rattail" files.

The HALF ROUND file is a general-purpose tool. The rounded side is used for curved surfaces and the flat face on flat surfaces. When you file an inside curve, use a round or half-round file whose curve most nearly matches the curve of the work.

Kits of small files, often called "Swiss Pattern" or "Jewelers" files, are used to fit parts of delicate mechanisms, and for filing work on instruments. Handle these small files carefully because they break easily.

Cuts and grades of files vary greatly. As mentioned before, they have either single-cut or double-cut teeth. The difference is apparent when you compare the files in fig. 1-1-30.

1.20.1A

Figure 1-1-30.—Single and double-cut files.

Single-cut files have rows of teeth cut parallel to each other. These teeth are set at an angle of about 65 degrees with the centerline. You will use single-cut files for sharpening tools, finish filing, and drawfiling. They are also the best tools for smoothing the edges of sheet metal.

Files with crisscrossed rows of teeth are double-cut files. The double cut forms teeth that are diamond-shaped and fast cutting. You will use double-cut files for quick removal of metal, and for rough work.

Files are also graded according to the spacing and size of their teeth, or their coarseness and fineness. Some of these grades are pictured in fig. 1-1-31. In addition to the three grades shown, you may use some DEAD SMOOTH files, which have very fine teeth, and some ROUGH files with very coarse teeth. The fineness or coarseness of file teeth is also influenced by the length of the file. When you have a chance, compare the actual size of the teeth of a 6-inch, single-cut smooth file and a 12-inch, single-cut smooth file; you will notice the 6-inch file has more teeth per inch than the 12-inch file.

1.20.3

Figure 1-1-31.—Grades of file teeth.

The flat or hand files most often used are the double-cut second cut file for rough work and the single-cut, smooth file for finish work.

For smoothing soft metals, such as aluminum and bearing metal, you may be supplied with a FLOAT-CUT file. It has large curved teeth and is worked with a planing action.

Never use a file unless it is equipped with a tight-fitting handle. If you use a file without the handle and it bumps something or jams to a sudden stop, the tang may be driven into your hand. To put a handle on a file tang, drill a hole in the handle, slightly smaller than the tang. Insert the tang end, and then tap the end of the handle to seat it firmly. Make sure you get the handle on straight.

As you file, the teeth of the file may "clog up" with some of the metal filings and scratch your work. This condition is known as PINNING. You can prevent pinning by keeping the file teeth clean. Rubbing chalk between the teeth will help prevent pinning, too, but the best method is to clean the file frequently with a FILE CARD or brush. A file card (fig. 1-1-32) has fine wire bristles. Brush with a pulling motion, holding the card parallel to the rows of teeth.

44.11

Figure 1-1-32.—File cleaner.

A new file should be broken in carefully by using it first on brass, bronze, or smooth cast iron. Just a few of the teeth will cut at first, so use a light pressure to prevent tooth breakage. Do not break in a new file by using it first on a narrow surface.

Protect the file teeth by hanging your files in a rack when they are not in use, or by placing them in drawers with wooden partitions. Your files should not be allowed to rust—keep them away from water and moisture. Avoid getting the files oily. Oil causes a file to slide across the work and prevents fast, clean cutting. Files that you keep in your toolbox should be wrapped in paper or cloth to protect their teeth and prevent damage to other tools.

Never use a file for prying or pounding. The tang is soft and bends easily. The body is hard and extremely brittle. Even a slight bend or a fall to the deck may cause a file to snap in two. Do not strike a file against the bench or vise to clean it—use a file card.

TWIST DRILLS

Making a hole in a piece of metal is generally a simple operation, but in most cases is an important and a precise job. A large number of different tools and machines have been designed so that holes may be made speedily, economically, and accurately in all kinds of material.

In order to be able to use these tools efficiently, it is well to become acquainted with them. The most common tool for making holes in metal is the twist drill. It consists of a cylindrical piece of steel with spiral grooves. One end of the cylinder is pointed while the other end is shaped so that it may be attached to a drilling machine. The grooves, usually called FLUTES, may be cut into the steel cylinder, or the flutes may be formed by twisting a flat piece of steel into a cylindrical shape.

The principal parts of a twist drill are the body, the shank, and the point. (See fig. 1-1-33.) The dead center of a drill is the sharp edge at the extreme tip end of the drill. It is formed by the intersection of the cone-shaped surfaces of the point and should always be in the exact center of the axis of the drill. The point of the drill should not be confused with the dead center. The point is the entire cone-shaped surface at the end of the drill.

The lip or cutting edge of a drill is that part of the point that actually cuts away the metal when drilling a hole. It is ordinarily as sharp as the edge of a knife. There is a cutting edge for each flute of the drill.

The lip clearance of a drill is the surface of the point that is ground away or relieved just back of the cutting edge of the drill. The strip along the inner edge of the body is called the margin. It is the greatest diameter of the drill and extends the entire length of the flute. The diameter of the margin at the shank end of the drill is smaller than the diameter at the point. This allows the drill to revolve without binding when drilling deep holes.

A tang is found only on tapered-shank drills. It is designed to fit into a slot in the socket or spindle of a machine. It may bear a portion of the driving torque, but its principal use is to make it easy to remove the drill from the socket of the driving machine.

The maintenance of twist drills and more about how to use them on specific jobs are discussed in a later section of this text.

REAMERS

Reamers are used to enlarge and true a hole. The reamer consists of three parts—the body, the shank, and the blades. The shank has a square

9118

132 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Figure 1-1-33.—Twist drill nomenclature.

tang to allow the reamer to be held with a wrench for turning. The main purpose of the body is to support the blades.

The blades on a reamer are made of steel and hardened to such an extent that they are brittle. For this reason you must be careful when using and storing the reamer to protect the blades from chipping. When you are reaming a hole, turn the reamer in the CUTTING DIRECTION ONLY. This will prevent chipping or dulling of the blades. Great care should be used to assure even, steady turning. Otherwise, the reamer will "chatter," causing the hole to become marked or scored. To prevent damage to the reamer while not in use, wrap it in an oily cloth and keep it in a box.

Reamers of the types shown in figure 1-1-34 are available in any standard size. They are also available in size variations of .001" for special work. Use a solid straight flute reamer when reaming a number of holes of the same size. This type lasts longer and is less expensive than the expansion reamer.

The solid spiral flute reamer is used where many similar holes are to be reamed. Many mechanics prefer it because it is less likely to chatter. The spiral reamer costs slightly more than the straight flute reamer.

5.10.1

Figure 1-1-34.—Above—solid spiral flute reamer.
Below—solid straight flute reamer.

For general purposes, an expansion reamer (fig. 1-1-35) is the most practical. This reamer can usually be obtained in standard sizes from 1/4 of an inch to 1 inch, by 32nds. It is designed to allow the blades to expand 1/32 of an inch. For example, the 1/4-inch expansion reamer will ream a 1/4-inch to a 9/32-inch hole. A 9/32-inch reamer will enlarge the hole from 9/32 of an inch to 5/16 of an inch. This range of adjustment allows a few reamers to cover sizes up to 1 inch.

5.10.2

Figure 1-1-35.—Expansion reamer.

Reamers are made of carbon steel and high-speed steel. In general, the cutting blades of a high-speed reamer lose their keenness more quickly than a carbon steel reamer. However, after that keenness is gone, it will last longer than the carbon reamer.

9119

132

COUNTERSINKS

Countersinking is the operation of beveling the mouth of a hole with a rotary tool called a countersink. (See fig. 1-1-36.) The construction of the countersink is similar to the twist drill. There are four cutting edges, which are taper ground, to the angle marked on the body.

Figure 1-1-36.—Countersink. 28.59(44)

A countersink is used primarily to set the head of a screw or rivet flush with the material in which it is being placed. Countersinks are made in a number of sizes. One size usually takes care of holes of several different sizes. That is, the same countersink can be used for holes from 1/4 inch to 1/2 inch in diameter. Remove only enough metal to set the screw or rivet head flush with the material. If you remove too much material the hole will enlarge and weaken the work.

Select the countersink with the correct lip angle to correspond with the screw or rivet head being used. These countersinks can be turned by any machine that will turn a twist drill.

BOLT CUTTERS

Bolt cutters (fig. 1-1-37) are giant shears with very short blades and long handles. The handles are hinged at one end. The cutters are at the ends of extensions which are jointed in such a way that the inside joint is forced outwards when the handles are closed, thus forcing the cutting edges together with great force. Bolt cutters are made in lengths of 18 to 36 inches. The larger ones will cut mild steel bolts and rods up to 1/2 inch. The material to be cut should be kept as far back in the jaws as possible.

44.12

Figure 1-1-37.—Bolt cutters.

Never attempt to cut spring wire or other tempered metal with bolt cutters. This will cause the jaws to be sprung or nicked. Adjusting screws near the middle hinges provide a means for ensuring that both jaws move the same amount when the handles are pressed together. Keep the adjusting screws just tight enough to ensure that the cutting edges meet along their entire length when the jaws are closed. The hinges should be kept well oiled at all times.

When using bolt cutters make sure your fingers are clear of the jaws and hinges. Take care that the bolt head or piece of rod cut off does not fly and injure you or someone else. If the cutters are brought together rapidly, sometimes a bolt-head or piece of rod being cut off will fly some distance.

Bolt cutters are fairly heavy, so make sure that they are stored in a safe place where they will not fall and injure someone.

WOODCUTTING HANDTOOLS

A man working with wood uses a large variety of handtools. He should be familiar with these tools, their proper names, the purpose for which they are used, and how to keep them in good condition.

In this section of the text, only the basic woodcutting tools are covered. It includes tools that any man in the Navy may have the occasion to use during his career.

HANDSAWS

The most common carpenter's handsaw consists of a steel blade with a handle at one end. The blade is narrower at the end opposite the handle. This end of the blade is called the "point" or "toe." The end of the blade nearest the handle is called the "heel" (fig. 1-1-38.) One edge of the blade has teeth, which act as two rows of cutters. When the saw is used, these teeth cut two parallel grooves close together. The chips (sawdust) are pushed out from between the grooves (kerf) by the beveled part of the teeth. The teeth are bent alternately to one side or the other, to make the kerf wider than the thickness of the blade. This bending is called the "set" of the teeth. (See fig. 1-1-39.) The

Figure 1-1-38.—Nomenclature of a handsaw.

Figure 1-1-39.—"Set" of hand saw teeth.

Figure 1-1-40.—Crosscut saw and ripsaw teeth.

number of teeth per inch, the size and shape of the teeth, and the amount of set depend on the use to be made of the saw and the material to be cut. Carpenter's handsaws are described by the number of points per inch. There is always one more point then there are teeth per inch. A number stamped near the handle gives the number of points of the saw.

Woodworking handsaws consist of RIPSAWS and CROSSCUT saws designed for general cutting. Ripsaws are used for cutting with the grain and crosscut saws are for cutting across the grain. A variety of other hand-operated saws, designed to serve special purposes, are designated by particular names, such as BACKSAW, DOVETAIL SAW, COPING SAW, and so on.

The major difference between a ripsaw and a crosscut saw is the shape of the teeth. A tooth with a square-faced chisel-type cutting edge, like the ripsaw tooth shown in figure 1-1-40, does a good job of cutting with the grain (called ripping), but a poor job of cutting across the grain (called crosscutting). A tooth with a beveled, knifetype cutting edge, like the crosscut saw tooth shown in the same figure, does a good job of cutting across the grain, but a poor job of cutting with the grain.

The more common types of saws used for special purposes are shown in figure 1-1-40. The BACKSAW is a crosscut saw designed for sawing a perfectly straight line across the face of a piece of stock. A heavy steel BACKING along the top of the blade keeps the blade perfectly straight.

The DOVETAIL saw is a special type of backsaw with a thin, narrow blade and a chisel-type handle.

The COMPASS saw is a long, narrow, tapering ripsaw designed for cutting out circular or other nonrectangular sections from within the margins of a board or panel. A hole is bored near the cutting line to start the saw. A KEYHOLE saw is simply a finer, narrower compass saw.

The COPING saw is used to cut along curved lines as shown in the figure.

The TWO-MAN CROSSCUT saw (fig. 1-1-42) is a double-handled saw used for heavy work, such as felling trees, cutting large trees into

9121

Figure 1-1-41.—Special saws.

logs, or sawing heavy bridge timbers. This saw is made of high-grade steel, with an arched blade 5 feet to 6 1/2 feet in length, approximately 8 inches wide at the middle and tapering to about 3 inches at each end. The cutting teeth are grouped in sections, usually with four cutting teeth to the section. Between sections are raker teeth which chisel out and remove the chips.

The two-man saw is operated by each man pulling the saw toward himself as far as it will go and then stopping, only guiding the saw as the other pulls it back. In vertical cutting, the weight of the saw creates enough pressure to make further forcing unnecessary. In horizontal cutting, only slight pressure on the saw is needed. Oil or paraffin on the blade will lubricate the blade and ease the work.

A saw that is not being used should be hung up or stowed in a toolbox. A toolbox designed for holding saws has notches that hold them on edge, teeth up. Stowing saws loose in a toolbox may allow the saw teeth to become dulled or bent by contacting other tools.

Before using a saw, be sure there are no nails or other edge-destroying objects in the line of the cut. When sawing out a strip of waste, do not break out the strip by twisting the saw blade. This dulls the saw, and may spring or break the blade.

Be sure that the saw will go through the full stroke without striking the floor or some other object. If the work cannot be raised high enough to obtain full clearance for the saw, you must carefully limit the length of each stroke.

Some right and wrong methods of using and caring for a saw are shown in figure 1-1-43.

PLANES

The plane is the most extensively used of the hand shaving tools. Most of the lumber handled

Figure 1-1-42.—Two-man crosscut saw.

44.13.2

1. WHEN WORK IS COMPLETE, HANG UP THE SAW.
2. DO NOT PILE TOOLS ON TOP OF THE BENCH SO AS TO DISTORT BLADE
3. LOOK CAREFULLY OVER REPAIR OR ALTERATION WORK; SEE THAT ALL NAILS ARE REMOVED TO AVOID CUTTING INTO METAL
4. STRIPS OF WASTE SHOULD NOT BE TWISTED OFF WITH BLADE, BUT BROKEN OFF WITH HAND OR MALLET.
5. SUPPORTING THE WASTE SIDE OF WORK WILL PREVENT SPLITTING OFF.
6. RAISE THE WORK TO A HEIGHT SUFFICIENT TO KEEP THE BLADE FROM STRIKING THE FLOOR. IF THE WORK CANNOT BE RAISED, LIMIT THE STROKE.

44.14

Figure 1-1-43.—Care of handsaws.

by anyone working with wood is dressed on all four sides, but when performing jobs such as fitting doors and sash, and interior trim work, planes must be used.

The large family of planes includes BENCH and BLOCK PLANES, designed for general surface smoothing and squaring, and other planes designed for special types of surface work.

The principal parts of a BENCH PLANE and the manner in which they are assembled, are shown in figure 1-1-44. The part at the rear that you grasp to push the plane ahead is called

Figure 1-1-44.—Parts of a bench plane. 29.12A

the HANDLE; the part at the front that you grasp to guide the plane along its course is called the KNOB. The main body of the plane, consisting of the bottom, the sides, and the sloping part which carries the plane iron, is called the FRAME. The bottom of the frame is called the SOLE, and the opening in the sole, through which the blade emerges, is called the MOUTH. The front end of the sole is called the TOE; the rear end, the HEEL.

A PLANE IRON CAP, which is screwed to the upper face of the plane iron, deflects the shaving upward through the mouth, as indicated in figure 1-1-45C, and thus prevents the mouth from becoming choked with jammed shavings. The edge of the cap should fit the back of the iron as shown in figure 1-1-45A, not as shown in figure 1-1-45B. The lower end of the plane iron cap should be set back 1/32 in. from the edge of the plane iron, as shown in figure 1-1-45A. The iron in a bench plane goes in bevel-down.

Figure 1-1-45.—Plane iron and plane iron cap.

The edge of the plane iron is brought into correct cutting position by the manipulation of first the ADJUSTING NUT and next the LATERAL ADJUSTMENT LEVER, as shown in figures 1-1-46 and 1-1-47. The adjusting nut moves the edge of the iron up or down; the lateral adjustment lever cants it to the right or left. To adjust the plane you hold it upside-down, sight along the sole from the toe, and work the adjusting nut until the edge of the blade appears. Then work the lateral adjustment lever until the edge of the blade is in perfect alinement with the sole, as shown in figures 1-1-46B and 1-1-46C. Then use the adjusting nut to give the blade the amount of protrusion you want. This amount will depend, of course, upon the depth of the cut you intend to make.

Figure 1-1-46.—Manipulation of the adjusting nut moves the plane iron up or down.

Figure 1-1-47.—Effect of manipulation of the lateral adjustment lever.

There are three types of bench planes (fig. 1-1-48): the SMOOTH plane, the JACK plane, and the JOINER plane (sometimes called the FORE plane or the GAGE plane). All are used primarily for shaving and smoothing with the grain; the chief difference is the length of the sole. The sole of the smooth plane is about 9 in. long, the sole of the jack plane about 14 in. long, and the sole of the jointer plane from 20 to 24 in. long.

The longer the sole of the plane is, the more uniformly flat and true the planed surface will be. Consequently, which bench plane you should use depends upon the requirements with regard to surface trueness. The smooth plane is, in general, smoother only; it will plane a smooth, but not an especially true surface in a short time. It is also used for cross-grain smoothing and squaring of end-stock.

The jack plane is the general "jack-of-all-work" of the bench plane group. It can take a deeper cut and plane a truer surface than the smooth plane. The joiner plane is used when the planed surface must meet the highest requirements with regard to trueness.

A BLOCK PLANE and the names of its parts are shown in figure 1-1-49. Note that the plane iron in a block plane does not have a plane iron cap, and also that, unlike the iron in a bench plane, the iron in a block plane goes in bevel-up.

9124 CSTE

29.12

Figure 1-1-48.—Types of bench planes and block plane.

The block plane, which is usually held at an angle to the work, is used chiefly for cross-grain squaring of end-stock. It is also useful, however, for smoothing all plane surfaces on very small work.

There are a great variety of special-purpose planes, only a few of which can be mentioned here. The RABBET-AND-FILLISTER plane is used to plane a RABBET (a groove cut on the edge or end of a piece of board) on an edge, as shown in figure 1-1-50. A FILLISTER is simply a rabbet which has been planed into the outer edge of a window sash bar. Before planing set the WIDTH GAGE on the plane to the desired width of the rabbet, and the DEPTH GAGE to the desired depth. To use this plane, set it on the edge with the width gage against the face of the board, and plane down until the further progress of the plane is stopped by the depth gage. The side edge of the plane iron must be set exactly flush with the side edge of the sole on the plane. The SPUR breaks trail, as it were, for the plane iron. Many rabbet-and-fillister planes do not have the spur.

44.15

Figure 1-1-50.—Rabbit-and-fillister plane.

29.12E

Figure 1-1-49.—Block plane nomenclature.

The ROUTER plane (fig. 1-1-51) is used to smooth the bottom of a groove that has been roughed out with a chisel. The way the plane works is evident in the illustration.

A BULL-NOSE plane is a small one-hand plane with the mouth located near the forward edge of the sole and the iron flush with one or both sides of the sole; it is used for planing close into corners. A PLOW plane uses irons of different widths. A UNIVERSAL plane is a complicated tool which is equipped with cutters of various shapes for planing moldings. A MATCHING PLANE cuts a groove on one piece and a tongue to "match" it on another.

Figure 1-1-51.—Router plane.

AUGER BITS

The woodworking and metal trades distinguish sharply between bits and drills and between boring and drilling. A woodworker never says that a hole is drilled in wood, but uses the term "bored" instead.

Bits are used for boring holes for screws, dowels, and hardware, as an aid in mortising (cutting a cavity in wood for joining members) and in shaping curves and for many other purposes. Like saws and planes, bits vary in shape and structure with the type of job to be done. Some of the most common bits are described in this section.

AUGER bits are screw-shaped tools consisting of six parts: the cutter, screw, spur, twist, shank, and tang. (See fig. 1-1-52.) The twist ends with two sharp points called the spurs, which score the circle, and two cutting edges which cut shavings within the scored circle. The screw centers the bit and draws it into the wood. The threads of the screw are made in three different pitches: steep, medium, and fine. The steep pitch makes for quick boring and thick chips, and the fine or slight pitch makes for slow boring and fine chips. For end-wood boring, a steep- or medium-pitch screw bit should be used because end wood is likely to be forced in between the fine screw threads, and that will prevent the screw from taking hold.

Figure 1-1-52.—Nomenclature of an auger bit.

The twist carries the cuttings away from the cutters and deposits them in a mound around the hole.

The sizes of auger bits are indicated in sixteenths of an inch and are stamped on the tang. A number 10 stamped on the tang means 10/16 or 5/8 in.; number 5 means 5/16 in. and so on. The most common woodworkers auger bit set ranges in size from 1/4 to 1 in.

Ordinary auger bits up to 1 in. in diameter are from 7 to 9 inches long. Short auger bits that are about 3 1/2 inches long are called DOWEL bits.

EXPANSIVE auger bits have adjustable cutters, for boring holes of different diameters (fig. 1-1-53.) Expansive bits are generally made in two different sizes. The largest size has three cutters and bores holes up to 4 inches in diameter. A scale on the cutter blade indicates the diameter of the hole to be bored.

More will be said on the maintenance, and the use of auger bits for specific jobs in a later section of this book.

Figure 1-1-53.—Expansion auger bit.

WOOD CHISELS

After a board has been sawed and planed to size, the next operation usually is to join it to

9126

Figure 1-1-54.—Tang and socket wood chisels.

another board or part of a structure. A wood chisel, figure 1-1-54, in conjunction with other tools, is indispensable when making most joints by hand.

A wood chisel is a steel tool fitted with a wooden or plastic handle. It has a single beveled cutting edge on the end of the steel part, or blade. According to their construction, chisels may be divided into two general classes: TANG chisels, in which part of the chisel enters the handle, and SOCKET chisels, in which the handle enters into a part of the chisel. (See fig. 1-1-54.)

A socket chisel is designed for striking with a wooden mallet (never a steel hammer), while a tang chisel is designed for hand manipulation only.

Wood chisels are also divided into types, depending upon their weights and thicknesses, the shape or design of the blade, and the work they are intended to do.

The shapes of the more common types of wood chisels are shown in figure 1-1-55. The FIRMER chisel has a strong, rectangular-cross-section blade, designed for both heavy and light work. The blade of the PARING chisel is relatively thin, and is beveled along the sides for the fine paring work. The BUTT chisel has a short blade, designed for work in hard-to-get-at places.

The butt chisel is commonly used for chiseling the GAINS (rectangular depressions) for the BUTT hinges on doors; hence the name. The MORTISING chisel has a narrow blade, designed for chiseling out the deep, narrow MORTISES for mortise-and-tenon joints. This work requires a good deal of levering out of chips;

Figure 1-1-55.—Shapes of common types of wood chisels.

9127

consequently, the mortising chisel is made extra thick in the shaft to prevent breaking.

A FRAMING chisel is shaped like a firmer chisel, but has a very heavy, strong blade, designed for work in rough carpentry.

Sections 5 and 6 of this course give you more on the maintenance and use of the wood chisel.

SCREWDRIVERS

A screwdriver is one of the most basic of basic handtools. It is also the most frequently abused of all handtools. It is designed for one function only—to drive and remove screws. A screwdriver should not be used as a pry bar, a scraper, a chisel, or a punch.

STANDARD SCREWDRIVER

There are three main parts to a standard screwdriver. The portion you grip is called the handle, the steel portion extending from the handle is the shank, and the end which fits into the screw is called the blade. (See fig. 1-1-56.)

1.14.1

Figure 1-1-56.—Nomenclature of a screwdriver.

The steel shank is designed to withstand considerable twisting force in proportion to its size, and the tip of the blade is hardened to keep it from wearing. There are times when a screwdriver may be used for gently levering two pieces apart, but you must remember that the shank is not designed to withstand severe bending and the hardened blade will easily break.

Standard screwdrivers are classified by size, according to the combined length of the shank and blade. The most common sizes range in length from 2 1/2 in. to 12 in. There are many screwdrivers smaller and some larger for special purposes. The diameter of the shank, and the width and thickness of the blade are generally proportionate to the length, but again there are special screwdrivers with long thin shanks, short thick shanks, and extra wide or extra narrow blades.

Screwdriver handles may be wood, plastic, or metal. When metal handles are used, there is usually a wooden hand grip placed on each side of the handle. In some types of wood- or plastic-handled screwdrivers the shank extends through the handle, while in others the shank enters the handle only a short way and is pinned to the handle. For heavy work, special types of screwdrivers are made with a square shank. They are designed this way so that they may be gripped with a wrench, but this is the only kind on which a wrench should be used.

When using a screwdriver it is important to select the proper size so that the blade fits the screw slot properly. This prevents burring the slot and reduces the force required to hold the driver in the slot.

PHILLIPS SCREWDRIVER

Recessed-head screws are now available under various trade names. These have a cavity of special shape formed in the head and require a specially shaped screwdriver. The most common type found is the Phillips head screw that requires a Phillips-type screwdriver. (See fig. 1-1-57.)

1.14.4

Figure 1-1-57.—Phillips-head screwdriver.

The head of a Phillips-type screw has a four-way slot into which the screwdriver fits. This prevents the screwdriver from slipping. Three standard sized Phillips screwdrivers handle a wide range of screw sizes. Their ability to hold helps to prevent damaging the slots or the work surrounding the screw. It is a poor practice to try to use a standard screwdriver on a Phillips screw because both the tool and screw slot will be damaged.

OFFSET SCREWDRIVER

The offset screwdriver is a handy tool for use in a tight spot. It is somewhat difficult to handle because the bit has a tendency to jump out of the slot and to burr the screw or surrounding work, if you are not careful. The offset screwdriver has one blade forged in line with the shank or handle and the other blade at right angles to the shank. (See fig. 1-1-58.) With such an arrangement, when the swinging space for the screwdriver is limited, you can change ends after each swing and thus work the screw in or out of the threaded hole. This type screwdriver is to be used when there is not sufficient space to use a standard screwdriver.

1.14.8

Figure 1-1-58.—Offset screwdriver.

RATCHET SCREWDRIVER

For fast easy work the ratchet screwdriver is extremely convenient, as it can be used one-handed and does not require the bit to be lifted out of the slot after each turn. It may be fitted with either a standard type bit or a special bit for recessed heads. The ratchet screwdriver is most commonly used by the woodworker for driving screws in soft wood.

A WORD OF CAUTION

You should never use a screwdriver to check an electrical circuit where the amperage is high. The current may be strong enough to arc and melt the screwdriver blade. And, never try to turn a screwdriver with a pair of pliers.

Do not hold work in your hand while using a screwdriver—if the point slips it can cause a bad cut. Hold the work in a vise, with a clamp, or on a solid surface. If that is impossible, you will always be safe if you follow this rule: NEVER GET ANY PART OF YOUR BODY IN FRONT OF THE SCREWDRIVER BLADE TIP. That is a good safety rule for any sharp or pointed tool.

The maintenance and repairing of screwdrivers is discussed in section 5 of this book.

PLIERS

The word PLIERS is a plural name for a single tool. Pliers are made in many styles and sizes and are used to perform many different operations. There is a definite field of usefulness for pliers, but they are emphatically not a substitute for a wrench. Pliers are used for holding and gripping small articles in situations where it may be inconvenient or impossible to use hands.

SLIP-JOINT PLIERS

Slip-joint pliers (fig. 1-1-59) are pliers with straight, serrated (grooved) jaws, and the screw or pivot with which the jaws are fastened together may be moved to either of two positions, in order to grasp small- or large-sized objects better.

To spread the jaws of slip-joint pliers, first spread the ends of the handles apart as far as possible. The slip-joint, or pivot, will not move to the open position. To close, again spread the handles as far as possible, then push the joint back into the closed position.

1.21.4a

Figure 1-1-59.—Slipjoint pliers.

Slip-joint combination pliers (fig. 1-1-60) are pliers similar to the slip-joint pliers just described, but with the additional feature of a side cutter at the junction of the jaws. This cutter consists of a pair of square cut notches, one on each jaw, which act like a pair of shears when an object is placed between them and the jaws are closed.

The cutter is designed to cut material such as soft wire and nails. To use the cutter, open

9129

1.21.4b

Figure 1-1-60.—Slipjoint combination pliers.

44.22

Figure 1-1-61.—Water pump pliers.

the jaws until the cutter on either jaw lines up with the other. Place the material to be cut as far back as possible into the opening formed by the cutter, and squeeze the handles of the pliers together. Do not attempt to cut hard material such as spring wire or hard rivets with the combination pliers. To do so will spring the jaws; and if the jaws are sprung, it will be difficult thereafter to cut small wire with the cutters.

VISE-GRIP PLIERS

Vise-Grip pliers (wrenches) can be used for holding objects regardless of their shape. A screw adjustment in one of the handles makes them suitable for several different sizes. The jaws of Vise-Grips may have standard serrations such as the pliers just described or may have a clamp-type jaw. The clamp-type jaws are generally wide and smooth and are used primarily when working with sheet metal.

Vise-Grip pliers have an advantage over other types of pliers in that you can clamp them on an object and they will stay. This will leave your hands free for other work.

WATER-PUMP PLIERS

Water-pump pliers were originally designed for tightening or removing water pump packing nuts. They were excellent for this job because they have a jaw adjustable to seven different positions. Water-pump pliers (fig. 1-1-61) are easily identified by their size, jaw teeth, and adjustable slip joint. The inner surface of the jaws consists of a series of coarse teeth formed by deep grooves, a surface adapted to grasping cylindrical objects.

Another version of the water-pump pliers is called Channel-Lock pliers. They are shaped approximately the same as the pliers just described, but the jaw opening adjustment is effected differently. Channel-Lock pliers have grooves on one jaw and lands on the other. The adjustment is effected by changing the position of the grooves and lands. The Channel-Lock pliers are less likely to slip from the adjustment setting when gripping an object.

DIAGONAL PLIERS

Diagonal cutting pliers (fig. 1-1-62) are used for cutting small, light material, such as wire and cotter pins in areas which are inaccessible to the larger cutting tools. Also, since they are designed for cutting only, larger objects can be cut than with the slip-joint pliers.

As the cutting edges are diagonally offset approximately 15 degrees, diagonal pliers are adapted to cutting small objects flush with a surface. The inner jaw surface is a diagonal straight cutting edge. Diagonal pliers should never be used to hold objects, because they exert a greater shearing force than other types of pliers of a similar size. The sizes of the diagonal cutting pliers are designated by the overall length of the pliers.

SIDE CUTTING PLIERS

Side-cutting pliers (sidecutters) are principally used for holding, bending, and cutting thin materials or small gage wire. Sidecutters vary in size and are designated by their overall length. The jaws are hollowed out on one side just forward of the pivot point of the pliers. Opposite the hollowed out portion of the jaws are the cutting edges.

When holding or bending light metal surfaces, the jaw tips are used to grasp the object. When holding wire grasp it as near one end as possible because the jaws will mar the wire. To cut small diameter wire the side cutting edge of the jaws near the pivot is used. Never use sidecutters to grasp large objects, tighten nuts, or bend

Fig. 1-1-62.—Diagonal-cutting pliers.

heavy gage metal, since such operations will spring the jaws.

Sidecutters are often called electrician or lineman pliers. They are used extensively for stripping insulation from wire and for twisting wire when making a splice.

MAINTENANCE OF PLIERS

Nearly all sidecutting pliers and diagonals are designed so that the cutting edges can be reground. Some older models of pliers will not close if material is ground from the cutting edges. When grinding the cutting edges never take any more material from the jaws than is necessary to remove the nicks. Grind the same amount of stock from both jaws.

NOTE: When jaws on pliers do not open enough to permit grinding, remove the pin that attaches the two halves of the pliers so that the jaws can be separated.

The serrations on the jaws of pliers must be sharp. When they become dull, the pliers should be held in a vise and the serrations recut by using a small 3-corner file.

Pliers should be coated with light oil when they are not in use. They should be stored in a toolbox in such a manner that the jaws cannot be injured by striking hard objects. Keep the pin or bolt at the hinge just tight enough to hold the two parts of the pliers in contact and always keep the pivot pin lubricated with a few drops of light oil.

PUNCHES

A hand punch is a tool that is held in the hand and struck on one end with a hammer. There are many kinds of punches designed to do a variety of jobs. Most punches are made of tool steel. The part held in the hand is usually octagonal shaped, or it may be knurled. This prevents the tool from slipping around in the hand. The other end is shaped to do a particular job. Figure 1-1-63 shows some of the most commonly used metal punches.

Figure 1-1-63.—Commonly used punches.

METAL PUNCHES

DRIFT punches, sometimes called "starting punches," have a long taper from the tip to the body. They are made that way to withstand the shock of heavy blows. They may be used for knocking out rivets after the heads have been chiseled off, or for freeing pins which are "frozen" in their holes.

After a pin has been loosened or partially driven out, the drift punch may be too large to finish the job. The followup tool to use is the PIN PUNCH. It is designed to follow through the hole without jamming. Always use the largest drift or pin punch that will fit the hole. These punches usually come in sets of three to five assorted sizes. Both of these punches will have flat points, never edged or rounded.

To remove a bolt or pin that is extremely tight, start with a drift punch that has a point diameter that is slightly smaller than the diameter of the object you are removing. As soon as it loosens, finish driving it out with a pin punch.

282-344 O - 67 - 3

Never use a pin punch for starting a pin because it has a slim shank and a hard blow may cause it to bend or break.

Another punch you will use a lot is the center punch. As the name implies, it is used for marking the center of a hole to be drilled. If you try to drill a hole without first punching the center, the drill will "wander" or "walk away" from the desired center. Another use of the center punch is to make corresponding marks on two pieces of an assembly to permit reassembly in the original positions.

The point of a center punch is accurately ground central with the shank, usually at a 60-degree angle, and is difficult to regrind by hand with any degree of accuracy. It is, therefore, advisable to take care of a center punch and not to use it on extremely hard materials.

Automatic center punches are useful for layout work. They are operated by pressing down on the shank by hand. An inside spring is compressed and released automatically, striking a blow on the end of the punch. The impression is light, but adequate for marking, and serves to locate the point of a regular punch when a deeper impression is required.

For assembling units of a machine an alinement (alining) punch is invaluable. It is usually about 1 foot long and has a long gradual taper. Its purpose is to line up holes in mating parts.

Hollow metal cutting punches are made from hardened tool steel. They are made in various sizes and are used to cut holes in light gage sheet metal.

Other punches have been designed for special uses. One of these is the soft-faced drift. It is made of brass or fiber and is used for such jobs as removing shafts, bearings, and wrist pins from engines. It is generally heavy enough to resist damage to itself, but soft enough not to injure the finished surface on the part that is being driven.

GASKET PUNCHES

You may have to make gaskets of rubber, cork, leather, or composition materials. For cutting holes in gasket materials a hollow shank gasket punch may be used. Gasket punches come in sets of various sizes to accommodate standard bolts and studs. The cutting end is tapered to a sharp edge to produce a clean, uniform hole. To use the gasket punch, place the gasket material to be cut on a piece of hard wood or lead so that the cutting edge of the punch will not be damaged. Then strike the punch with a hammer, driving it through the gasket where holes are required.

MEASURING TOOLS

The ability to lay out work and to measure accurately depends upon the correct use of measuring tools and the ease with which the graduations on these tools are read. While each of the measuring tools explained in this section is used for a specific purpose, they are all graduated according to the same system of linear measure.

There are many different types of measuring tools in use in the Navy. Where exact measurements are required a micrometer caliper (mike) is used. Such a caliper when properly used, gives measurements to within .0001 of an inch accuracy. The common rule or tape will suffice for most measurements that you will need.

RULES AND TAPES

Figure 1-1-64 shows some of the types of rules and tapes commonly used in the Navy. Of all measuring tools, the simplest and most common is the steel rule. This rule is usually 6 or 12 inches, although other lengths, such as 4 in., 18 in., and longer, are available. Steel rules may be flexible or nonflexible, but the thinner the rule, the easier it is to measure accurately because the division marks are closer to the work.

Figure 1-1-64.—Some common types of rules.

Generally a rule has four sets of graduations, one on each edge of each side. The longest lines represent the inch marks. On one edge, each inch is divided into 8 equal spaces; so each space represents 1/8 in. The other edge of this side

9132

is divided into sixteenths. The 1/4-in. and 1/2-in. marks are commonly made longer than the smaller division marks to facilitate counting, but the graduations are not, as a rule, numbered individually, as they are sufficiently far apart to be counted without difficulty. The opposite side is similarly divided into 32 and 64 spaces per inch, and it is common practice to number every fourth division for easier reading.

There are many variations of the common rule. Sometimes the graduations are on one side only, sometimes a set of graduations is added across one end for measuring in narrow spaces, and sometimes only the first inch is divided into 64ths, with the remaining inches divided into 32nds and 16ths.

For measuring lengths greater than 18 in., folding steel, wood, or aluminum rules can be used. These are called folding rules and are usually 2 to 6 feet long. The folding rules cannot be relied on for extremely accurate measurements because a certain amount of play develops at the joints after they have been used for a while.

Steel tapes are made from 6 to about 100 ft. in length. In the shorter lengths, these are frequently made with a curved cross section so that they are flexible enough to roll up, but remain rigid when extended. Long, flat tapes require support over their full length when measuring, or the natural sag will cause an error in reading.

The flexible-rigid tapes are usually contained in metal cases into which they wind themselves when a button is pressed, or into which they can be easily pushed. A hook is provided at one end to hook over the object being measured so one man can handle it without assistance. On some models, the outside of the case can be used as one end of the tape when measuring inside dimensions.

Rules and tapes should be handled carefully and kept lightly oiled to prevent rust. Never allow the edges of measuring devices to become nicked by striking them with hard objects. They should preferably be kept in a wooden box when not in use.

To avoid kinking tapes, pull them straight out from their cases—do not bend them backward. With the windup type, always turn the crank clockwise—turning it backward will kink or break the tape. With the spring-wind type, guide the tape by hand. If it is allowed to snap back, it may be kinked, twisted, or otherwise damaged.

SIMPLE CALIPERS

Simple calipers are used in conjunction with a scale to measure diameters. The calipers most commonly used in the Navy are shown in fig. 1-1-65.

Outside calipers for measuring outside diameters are bow-legged; those used for inside diameters have straight legs with the feet turned called firm-joint calipers. These calipers are adjusted by pulling or pushing the legs to open or close them. Fine adjustment is made by tapping one leg lightly on a hard surface to close them, or by turning them upside down and tapping on the joint end to open them. A variant of the firm-joint has a small screw for making fine adjustments.

Spring-joint calipers have the legs joined by a strong spring hinge and linked together by a screw and adjusting nut.

For measuring chamfered cavities, or for use over flanges, transfer calipers are available. They are equipped with a small auxiliary leaf attached to one of the legs by a screw. (See fig. 1-1-65.) The measurement is made as with ordinary calipers; then the leaf is locked to the leg. The legs may be opened or closed as needed to clear the obstruction, then brought back and locked to the leaf again, thus restoring them to the original setting.

A different type of caliper is the hermaphrodite, sometimes called odd-leg caliper. This has one straight leg ending in a sharp point, sometimes removable, and one bow leg. The hermaphrodite caliper is used chiefly for locating the center of a shaft, or for locating a shoulder.

Keep calipers clean and lightly oiled, but do not overoil the joint of firm joint calipers or you may have difficulty in keeping them tight. Do not throw them around or use them for screwdrivers or pry bars. Remember they are measuring instruments and must be used only for the purpose for which they are intended.

CALIPER SQUARE

The main disadvantage to ordinary calipers is that they do not give a direct reading. It is necessary to measure across the points of a caliper with an ordinary scale to get the measurement. To overcome this, the caliper square, (fig. 1-1-66) sometimes called a slide caliper, is available.

Figure 1-1-65.—Simple calipers—noncalibrated.

Slide calipers can be used for measuring outside, inside, and other dimensions. One side of the caliper is used as a measuring rule, while the scale on the opposite side is used in measuring outside and inside dimensions. Graduations on both scales are in inches and fractions thereof. A locking screw is incorporated to hold the slide caliper jaws in position during use. Stamped on the frame are two words, "IN" and "OUT," to be used in reading the scale while making inside and outside measurements, respectively.

Figure 1-1-66.—Caliper square (slide caliper).

Pocket slide calipers are commonly made in 3-in. and 5-in. sizes and are graduated to read in 32nds and 64ths. Pocket slide calipers are valuable when extreme precision is not required. They are frequently used for duplicating work when the expense of fixed gages is not warranted.

VERNIER SCALE

When extreme accuracy and close tolerances are needed, measuring tools that incorporate a vernier scale may be used.

The fundamental idea behind the vernier scale is to divide a line of known length into equal parts, and to compare the length of each part with those on a line the same length as the first one, but divided into one less part.

Figure 1-1-67 shows a bar 1 inch long divided by graduations into 40 parts so that each graduation indicates one-fortieth of an inch (0.025 inch). Every fourth graduation is numbered; each number indicates tenths of an inch (4X0.025 inch). The vernier, which slides along the bar, is graduated into 25 divisions which together, are as long as 24 divisions on the bar. Consequently, each division of the vernier is 0.001 inch smaller than each division on the bar. Verniers that are calibrated as just explained are known as English-measure verniers. The metric-measure vernier is read the same, except that the units of measurement are in millimeters, and the fractions are all decimal fractions.

One of the most common applications of the vernier scale is the vernier caliper.

Figure 1-1-67.—English-measure vernier scale.

VERNIER CALIPER

Perhaps the most distinct advantage of the vernier caliper is the ability to provide very accurate measurements over a large range. It can be used for both internal and external surfaces. Pocket models usually measure from zero to 3 in., but sizes are available all the way to 4 ft.

A vernier caliper (fig. 1-1-68) consists of an L-shaped member with a scale engraved on the long shank. A sliding member is free to move on the bar and carries a jaw which matches the arm of the L. The vernier scale is engraved on a small plate that is attached to the sliding member.

READING A VERNIER CALIPER

Figure 1-1-69 A illustrates the English measure vernier caliper. Figure B shows an enlarged view of the vernier used. As you can see in this figure, when the zero on the vernier coincides with the 1-inch mark, no other lines coincide until the 25th mark on the vernier. Now count the division on the inch rule. There are only 24 such divisions (each equal to 1/40 inch) opposite the 25 divisions on the vernier. This means that the vernier divisions are a little narrower than those on the rule. Since each of the 24 spaces on the rule equals 1/40" the whole vernier scale is 24 X 1/40" or 24 X 0.0025 = 0.600". Thus one division on the vernier equals 1/25 of 0.300", or 0.24". So, the difference between a division on the vernier and on the rule is 0.025" - 0.024" = 0.001". When measuring, therefore, for each division on the vernier, count from its zero point to the line which coincides with a line on the rule, and to the reading on the rule at this point, add 0.001".

To read the caliper in figure 1-1-69C, write down in a column the number of inches (1.000"), of tenths of an inch (0.400"), and of thousandths of an inch the zero mark on the vernier is from the zero mark on the rule. Because the zero mark on the vernier is a little past a 0.025" mark, write down the 0.025" and then note the highest number on the vernier where a line on the vernier concides with one on the rule. In this case (fig. 1-1-69C) it is at the 0.011" line on the vernier, so you also write the 0.011" in the column which will then look like this:

1.000"
.400"
.025"
.011"
———
1.436"

9135

Figure 1-1-68.—Vernier caliper.

The reading on the caliper shown in figure 1-1-69 C is 1.436", and was obtained by adding four separate "readings." After a little practice you will be able to make these calculations mentally.

Now try to read the settings of the two verniers shown in figure 1-1-69 D. Follow the above procedure. You should read 2.350" on the first setting and 2.368" on the second one.

To read a metric-measure vernier, note the number of millimeters, and the 0.25 millimeter if the setting permits, that the zero on the vernier has moved from the zero on the scale. Then add the number of hundredths of a millimeter indicated by the line on the vernier that coincides with a line on the scale.

For example, figure 1-1-70 A shows the zero graduation on the vernier coinciding with a 0.5-mm. graduation on the scale. This indicates that 0.08 mm. should be added to the scale reading. The reading in figure 1-1-70 B equals 38.00 mm. + 0.50 mm. + 0.08 mm. = 38.58 mm.

If a vernier caliper is calibrated in either English measure or in metric measure, usually one side will be calibrated to take outside measurements and the other to take inside measurements directly. The vernier plate for inside measurements is set to compensate for the thickness of the measuring points of the tools. But if a vernier caliper is calibrated for both English and metric measure, one of the scales will appear on one side and one on the other. Then it will be necessary, when taking inside measurements over the measuring points, to add certain amounts to allow for their thickness; for example, the following table shows the amounts to be added for various sizes of vernier calipers:

Measuring Point Allowances

Size of Caliper	English Measure	Metric Measure
6" or 150 mm .	Add 0.250"...	Add 6.35 mm.
12" or 300 mm .	.300"...	7.62 mm.
24" or 600 mm .	.300"...	7.62 mm.
36" or 600 mm .	.500"...	12.70 mm.

CARE OF THE VERNIER CALIPER

The inside faces of the jaws and the outside of the tips must be treated with great care. If they become worn, or the jaws bent, the tool will no longer give accurate readings. The accuracy of vernier calipers should be checked periodically by measuring an object of known dimension. Vernier calipers can be adjusted when they are not accurate, but the manufacturer's recommendations for this adjustment must be followed.

Keep vernier calipers lightly oiled to prevent rust and keep them stored away from heavy tools. A vernier caliper looks something like a monkey wrench, but never use it as such.

MICROMETER

In much wider use than the vernier caliper is the micrometer commonly called the "mike." It is important that a person who is working with machinery or in a machine shop thoroughly understand the mechanical principles, construction, use, and care of the micrometer. Figure 1-1-71 shows an outside micrometer caliper

Figure 1-1-71.—Nomenclature of an outside micrometer caliper.

with the various parts clearly indicated. Before attempting to use the tool, you should become familiar with the nomenclature, especially the frame, anvil, spindle, sleeve (barrel), and thimble. Micrometers are needed to measure distances to the nearest one thousandth of an inch. The measurement is usually expressed or written as a decimal; so you must know the method of writing and reading decimals.

TYPES OF MICROMETERS

There are three types of micrometers that are most commonly used throughout the Navy: the outside micrometer caliper (including the screw thread micrometer), the inside micrometer, and the depth micrometer. (See fig. 1-1-72.) The outside micrometer is used for measuring outside dimensions, such as the diameter of a piece of round stock. The screw thread micrometer is used to determine the pitch diameter of screws. The inside micrometer is used for measuring inside dimensions, as for example, the inside diameter of a tube or hole, the bore of a cylinder, or the width of a recess. The depth micrometer is used for measuring the depth of holes or recesses.

SELECTING THE PROPER MICROMETER

The types of micrometers commonly used are made so that the longest movement possible between the spindle and the anvil is 1 inch. This movement is called the "range." The frames of micrometers, however, are available in a wide variety of sizes, from 1 inch up to as large as 24 inches. The range of a 1-inch micrometer is from 0 to 1 inch; in other words, it can be used on work where the part to be measured is 1 inch or less. A 2-inch micrometer has a range from 1 inch to 2 inches, and will measure only work between 1 and 2 inches thick; a 6-inch micrometer has a range from 5 to 6 inches, and will measure only work between 5 and 6 inches thick. It is necessary, therefore, that the mechanic in selecting a micrometer first find the approximate size of the work to the nearest inch, and then select a micrometer that will fit it. For example, to find the exact diameter of a piece of round stock; use a rule and find the approximate diameter of the stock. If it is found to be approximately 3 1/4 inches, a micrometer with a 3- to 4-inch range would be required to measure the

Figure 1-1-72.—Common types of micrometers.

exact diameter. Similarly, with inside and depth micrometers, rods of suitable lengths must be fitted into the tool to get the approximate dimension within an inch, after which the exact measurement is read by turning the thimble. The size of a micrometer is given as the size of the largest work it will measure.

READING A MICROMETER CALIPER

The spindle and the thimble of the micrometer caliper illustrated in figure 1-1-71, which shows the parts of a 1-inch micrometer caliper, are in one piece. The spindle is moved toward or away from the anvil by turning the thimble.

The sleeve and thimble scales of the micrometer caliper have been enlarged in figure 1-1-73. To understand these scales, you need to know that the threaded section on the spindle, which revolves, has 40 threads per inch. Therefore, every time the thimble completes a revolution, the spindle advances or recedes 1/40" (0.025").

Notice in figure 1-1-73 that the horizontal line on the sleeve is divided into 40 equal parts per inch. Every fourth graduation is numbered 1, 2, 3, 4, etc., representing 0.100", 0.200",

Figure 1-1-73.—Sleeve and thimble scales of a micrometer (enlarged).

etc. When you turn the thimble so that its edge is over the first sleeve line past the "0" on the thimble scale, the spindle has opened 0.025". If you turn the spindle to the second mark, it has moved 0.025" plus 0.025" or 0.050". You use the scale on the thimble to complete your reading when the edge of the thimble stops between graduated lines. This scale is divided into 25 equal parts, each part representing 1/25 of a turn. And 1/25 of 0.025" is 0.001". As you can see, every fifth line on the thimble scale is marked, 5, 10, 15, etc. The thimble scale, therefore, permits you to take very accurate readings to the thousandths of an inch, and, since you can estimate between the divisions on the thimble scale, fairly accurate readings to the ten thousandth of an inch are possible.

The closeup in figure 1-1-74 will help you understand how to take a complete micrometer reading. Count the units on the thimble scale and add them to the reading on the sleeve scale. The reading in the figure shows a sleeve reading of 0.250" (the thimble having stopped slightly more than halfway between 2 and 3 on the sleeve) with the 10th line on the thimble scale coinciding with the horizontal sleeve line. Number 10 on this scale means that the spindle has moved away from the anvil an additional 10 X 0.001" or 0.010". Add this amount to the 0.250" sleeve reading, and the total distance is 0.260".

4.20.2

Figure 1-1-74.—Read a micrometer caliper.

Read each of the micrometer settings in figure 1-1-75 so that you can be sure of yourself when you begin to use this tool on the job. The correct readings are given following the figure so that you can check yourself.

Figure 1-1-76 shows a reading in which the horizontal line falls between two graduations on the thimble scale and is closer to the 15 graduation than it is to the 14. To read this to THREE decimal places, refer to figure 1-1-76 A. To read it to FOUR decimal places, estimate the number of tenths of the distance between thimble-scale graduations the horizontal line has fallen. Each tenth of this distance equals one ten-thousandth (0.0001) of an inch. Add the ten-thousandths to the reading as shown in figure 1-1-76 B.

Reading a Vernier Micrometer Caliper

Many times you will be required to work to exceptionally precise dimensions. Under these conditions it is better to use a ten-thousandth micrometer. This instrument has a third scale which is a vernier scale, shown in figure 1-1-77, that furnishes the fine readings between the lines on the thimble rather than making you estimate. The 10 spaces on the vernier are equivalent to 9 spaces on the thimble. Therefore, each unit on the vernier scale is equal to 0.0009" and the difference between the sizes of the units on each scale is 0.0001".

When a line on the thimble scale does not coincide with the horizontal sleeve line, you can determine the additional space beyond the readable thimble mark by finding which vernier mark coincides with a line on the thimble scale. Add this number, as that many ten-thousandths of an inch, to the original reading. In figure 1-1-78 see how the second line on the vernier scale coincides with a line on the thimble scale.

This means that the 0.011 mark on the thimble scale has been advanced an additional 0.0002" beyond the horizontal sleeve line. When you add this to the other readings, the reading will be 0.200 + 0.075 + 0.011 + 0.0002 or 0.2862", as shown.

CARE OF MICROMETERS

Keep micrometers clean and lightly oiled. Make sure they are placed in a case or box when they are not in use. Anvil faces must be protected from damage and must not be cleaned with emery cloth or other abrasive.

If a 1 inch micrometer caliper does not read zero when the spindle touches the anvil, and both are clean at the point of contact, the zero

Figure 1-1-77.—Vernier scale on a micrometer.

setting should be corrected. This will eliminate the necessity of adding or subtracting a "zero correction" numerically to each reading as would otherwise be necessary if this adjustment were not made.

The zero setting on all micrometers is not made in exactly the same way. Refer to either the instructions that come with the micrometer or to the manufacturer's catalog for specific directions for a particular tool.

Master test gages are sometimes supplied for checking the accuracy of the micrometer. If these are not available, gage blocks can be used for this purpose. To adjust a micrometer larger than a 1-inch size, a master test gage or gage block must be used between the anvil and spindle to test for the correct zero reading.

SQUARES

Squares are primarily used for testing and checking trueness of an angle or for laying out lines on materials before cutting. Most squares have a rule marked on their edge and may also be used for measuring. There are several types of squares commonly used in the Navy by personnel working with wood and metal.

CARPENTER'S SQUARE

The size of a carpenter's steel square is usually 12 inches x 8 inches, 24 inches x 16 inches, or 24 inches x 18 inches. The 12- or 24-inch side is called the blade and the 8-, 16-, or 18-inch side, which is at right angles to the blade, is called the tongue. (See fig. 1-1-78.) The flat sides of the blade and the tongue are graduated in inches and fractions of an inch. Both the blade and the tongue may be used as a rule and also as a straightedge in layout operations. Besides the inch and fractional graduations on the square, several tables (fig. 1-1-79) are marked on it.

The carpenter's square enables you, when working with wood, to lay out guidelines for

Figure 1-1-78.—Read a vernier micrometer caliper.

9142

29.23A

Figure 1-1-79.—Carpenters square.

cutting rafters, oblique joints, stairs, and so forth. You can perform many calculations with the aid of the tables and graduations marked on the blade and tongue of the square. The most common uses for this square are laying out and squaring up large stock and large patterns, and for testing the flatness and squareness of large surfaces by placing the square at right angles to adjacent surfaces and observing if light shows between the work and the square.

TRY SQUARE

The try square (fig. 1-1-80) consists of two parts at right angles to each other; a thick wood or iron stock and a thin, steel blade. Most try squares are made with the blades graduated in inches and fractions of an inch. The blade length varies from 2 inches to 12 inches. This square is used for setting or checking lines or surfaces which have to be at right angles to each other. The carpenter's square can be used for the same purpose, but is often too large to use accurately.

SLIDING T BEVEL

The sliding T-bevel (fig. 1-1-81) is an adjustable try square with a slotted beveled blade. Blades are normally 6 or 8 inches long. The sliding T-bevel is used for laying out angles other than right angles, and for testing constructed angles such as bevels. These squares are made with either wood or metal handles.

COMBINATION SQUARE

A combination square that is equipped with a SQUARE HEAD, PROTRACTOR HEAD, and a CENTER HEAD is the most versatile layout tool that is used by Navy personnel. As its name implies, it combines the functions of several

9143

44.25

Figure 1-1-80.—Common try square.

44.26

Figure 1-1-81.—Sliding T-bevel.

tools, and serves a wide variety of purposes. It consists of a hardened steel scale and the movable heads. (See fig. 1-1-82.)

The SQUARE HEAD may be adjusted to any position along the scale and clamped securely, or may be removed entirely. It can thus serve as a depth gage, height gage, or scribing gage. Two of the faces of the head are ground at right angles to each other, and a third face at 45 degrees. A small spirit level is built into the head for checking whether surfaces are plumb, and a small scriber is housed in a hole in the end of the head for marking layout lines.

The CENTER HEAD can be slid on to the blade in place of the stock head. This is a V-shaped member so designed that the center of the 90 degree V will lie exactly along one edge of the blade. This attachment is useful when locating the exact center of round stock.

The PROTRACTOR HEAD, commonly called a bevel protractor, can be attached to the scale, adjusted to any position on it, and turned and locked at any desired angle. Some types have a shoulder on only one side of the blade, others have it extending on both sides. Angular graduations usually read from 0 to 180 degrees both ways, permitting the supplement of the angle to be read. A spirit level may be included on some models forming, in effect, an adjustable level to show any required degree.

CARE OF SQUARES

Make certain the blades, heads, dials, and all accessories are clean. Apply a light coat of oil on all metal surfaces to prevent rusting when not in use. Do not use squares for purposes other than those intended. When storing squares or bevels for long periods of time, apply a liberal amount of oil or rust-preventive compound to all surfaces, wrap in oiled paper or cloth, and place in containers or on racks away from other tools.

MISCELLANEOUS MEASURING GAGES

There are a number of miscellaneous tools that are called gages and may be used for measuring or testing and setting distances. Some of the gages that will be discussed here will also be useful for layout work as well as for measuring.

DEPTH GAGE

A depth gage is an instrument for measuring the depth of holes, slots, counterbores, recesses, and the distance from a surface to some recessed part. The RULE DEPTH GAGE and the MICROMETER DEPTH GAGE are the most commonly used in the Navy. (See fig. 1-1-83.)

The rule depth gage is a graduated rule with a sliding head designed to bridge a hole or slot, and to hold the rule perpendicular to the surface on which the measurement is taken. This type has a measuring range of 0 to 5 inches. The sliding head has a clamping screw so that it may be clamped in any position. The sliding head has a flat base which is perpendicular to the axis of the rule and ranges in size from 2 to 2 5/8 inches in width and from 1/8 to 1/4 inch in thickness.

The micrometer depth gage consists of a flat base attached to the barrel (sleeve) of a micrometer head. These gages have a range from 0 to 9 inches, depending on the length of extension rod used. The hollow micrometer screw (the threads on which the thimble rotates) itself has a range of either 1/2 or 1 inch. Some are provided with a ratchet stop. The flat base ranges in size from 2 to 6 inches. Several extension rods are normally supplied with this type of gage.

29.25

Figure 1-1-82.—Combination square set.

SURFACE GAGE

A surface gage is a measuring tool generally used to transfer measurements to work by scribing a line, and to indicate the accuracy or parallelism of surfaces.

The surface gage (fig. 1-1-84) consists of a base with an adjustable spindle to which may be clamped a scriber or an indicator. Surface gages are made in several sizes and are classified by the length of the spindle, the smallest spindle being 4 inches long, the average 9 or 12 inches long and the largest 18 inches. The scriber is fastened to the spindle with a clamp. The bottom and the front end of the base of the surface gage have deep V-grooves cut in them, which allow the gage to measure from a cylindrical surface.

The spindle of a surface gage may be adjusted to any position with respect to the base and tightened in place with the spindle nut. The rocker adjusting screw provides for the finer adjustment of the spindle by pivoting the spindle rocker bracket. The scriber can be positioned at any height and in any desired direction on the spindle by tightening the scriber nut. The scriber may also be mounted directly in the spindle nut mounting, in place of the spindle, and used where the working space is limited and the height of the work is within range of the scriber.

SURFACE PLATE

A surface plate provides a true, smooth, plane surface. It is a flat-topped steel or cast iron plate that is heavily ribbed and reinforced on the under side. (See fig. 1-1-85.) It is often used in conjunction with a surface gage as a level base on which the gage and part to be measured are placed to obtain accurate measurements.

The surface plate can also be used for testing parts that must have flat surfaces. Before using the plate for testing smear a thin film of Prussian blue, or some other color pigment, on its surface; then rub the flat surface to be tested over the plate and the color pigment will stick to the high spots.

The surface plate should be covered when not in use to prevent scratching, nicking, and denting. It must be handled carefully to prevent warping (twisting). Never use the surface plate

9145

Figure 1-1-83.—Types of depth gages.

44.27

as an anvil or workbench—except for precision layout work (marking and measuring).

THICKNESS (FEELER) GAGE

Thickness (feeler) gages are fixed in leaf form, to permit the checking and measuring of small openings such as contact points, narrow slots, and so forth. They are widely used to check the flatness of parts in straightening and grinding operations and in squaring objects with a try square.

Thickness gages are made in many shapes and sizes; usually 2 to 26 blades are grouped into one tool and graduated in thousandths of an inch. (See fig. 1-1-86.) Most thickness gage blades are straight, while others are bent at the end at 45 and 90 degree angles. Some thickness gages are grouped so that there are several short and several long blades together. Thickness gages are also available in single blades and in strip form for specific measurements. For convenience, groups of thickness blades are equipped with a locking screw in the case that locks the blade to be used in the extended position.

THREAD GAGE

Thread gages (screw-pitch gages) are used to determine the pitch and the number of threads

28.25.3

Figure 1-1-84.—Surface gage.

44.28

Figure 1-1-85.—Surface plate.

per inch. (See fig. 1-1-87.) They consist of thin leaves whose edges are toothed to correspond to standard thread sections.

To measure the pitch of a thread, compare it with the standards of the gage, holding a gage leaf to the thread being gaged until you find an exact fit. If possible, look at the fit toward a source of light, since a difference of one thread

4.19(44)

Figure 1-1-86.—Thickness (Feeler) gages.

per inch, in the finer threads, is not easily detected.

The number of threads per inch is indicated by the numerical value on the blade which is found to fit the threads. Using this value as a basis, correct sizes of nuts, bolts, tap cutters, and die cutters are selected for use on the threads.

If the number of threads per inch on a nut equal the number of threads per inch on a bolt, the nut can be successfully applied without danger of stripping the threads on either.

WIRE GAGE

The wire gage (fig. 1-1-88) is used for gaging metal wire, and a similar gage is used to check the size of hot and cold rolled steel, sheet and plate iron, and music wire. The wire gage is circular in shape with cutouts in the outer perimeter. Each cutout gages a different size wire from 0 to 36 of the English Standard Wire Gage. A different gage is used for American Standard wire, and still another for U.S. Standard sheet and plate iron and steel.

TELESCOPING GAGE

Telescoping gages are used for measuring the inside size of slots or holes up to 6 inches in width or diameter. They are T-shaped tools in which the shaft of the T is used as a handle, and the crossarm used for measuring. (See fig. 1-1-89.) The crossarms telescope into each other and are held out by a light spring. To use the gage the arms are compressed, placed in the hole to be measured, and allowed to expand. A twist of the locknut on top of the handle locks the

9147

5.14(44)

Figure 1-1-87.—Screw pitch gage.

44.29

Figure 1-1-89.—Small hole and telescoping gages.

5.15.1

Figure 1-1-88.—English standard wire gage.

arms. The tool may then be withdrawn and the distance across the arms measured.

These tools are commonly furnished in sets, the smallest gage for measuring distances from 5/16 to 1/2 inch, and the largest for distances from 3 1/2 to 6 inches.

SMALL HOLE GAGE

For measuring smaller slots or holes than the telescoping gages will measure, small hole gages can be used. These gages come in sets of four or more and will measure distances of approximately 1/8 to 1/2 inch.

The small hole gage (fig. 1-1-89) consists of a small, split, ball-shaped member mounted on the end of a handle. The ball is expanded by turning a knurled knob on the handle until the proper feel is obtained, and then the size of the ball-shaped member on the end of the gage can be measured with an outside micrometer caliper. On some types of small hole gages, the ball is flattened at the bottom near the centerline to permit use in shallow holes and recesses.

MARKING GAGES

A marking gage is used to mark off guidelines parallel to an edge, end, or surface of a piece of wood or metal. It has a sharp spur or pin that does the marking.

Marking gages (fig. 1-1-90) are made of wood or steel. They consist of a graduated

44.30

Figure 1-1-90.—Marking gages.

9148

beam about 8 inches long on which a head slides. The head can be fastened at any point on the beam by means of a thumbscrew. The thumbscrew presses a brass shoe tightly against the beam and locks it firmly in position. The steel pin or spur that does the marking projects from the beam about 1/16 inch.

TAPS AND DIES

Taps and dies are used to cut threads in metal, plastics, or hard rubber. The taps are used for cutting internal threads, and the dies are used to cut external threads. There are many different types of taps. However, the most common are the taper, plug, bottoming, and pipe taps. (See fig. 1-1-91.)

The taper (starting) hand tap has a chamfer length of 8 to 10 threads. These taps are used when starting a tapping operation and when tapping through holes.

Plug hand taps have a chamfer length of 3 to 5 threads and are designed for use after the taper tap.

Bottoming hand taps are used for threading the bottom of a blind hole. They have a very short chamfer length of only 1 to 1 1/2 threads for this purpose. This tap is always used after the plug tap has already been used. Both the taper and plug taps should precede the use of the bottoming hand tap.

Pipe taps are used for pipe fittings and other places where extremely tight fits are necessary. The tap diameter, from end to end of threaded portion, increases at the rate of 3/4 inch per foot. All the threads on this tap do the cutting, as compared to the straight taps where only the nonchamfered portion does the cutting.

Dies are made in several different shapes and are of the solid or adjustable type. The square pipe die (fig. 1-1-92) will cut American Standard Pipe Thread only. It comes in a variety of sizes for cutting threads on pipe with diameters of 1/8 inch to 3 inches.

A rethreading die (fig. 1-1-92) is used principally for dressing over bruised or rusty threads on screws or bolts. It is available in a variety of sizes for rethreading American Standard Coarse and Fine threads. These dies are usually hexagon in shape and can be turned with a socket, box, open-end, or any wrench that will fit. Rethreading dies are available in sets of 6, 10, 14, and 28 assorted sizes in a case.

Figure 1-1-91.—Types of common taps.

11.5.1

9149

11.5.4

Figure 1-1-92.—Types of solid dies.

Round split adjustable dies (fig. 1-1-93) are called "Button" dies and can be used in either hand diestocks or machine holders. The adjustment in the screw adjusting type is made by a fine-pitch screw which forces the sides of the die apart or allows them to spring together. The adjustment in the open adjusting types is made by means of three screws in the holder, one for expanding and two for compressing the dies. Round split adjustable dies are available in a variety of sizes to cut American Standard Coarse and Fine threads, special form threads, and the standard sizes of threads that are used in Britain and other European countries. For hand threading, these dies are held in diestocks (fig. 1-1-94). One type die stock has three pointed screws that will hold round dies of any construction, although it is made specifically for open adjusting-type dies.

Two piece collet dies (fig. 1-1-93) are used with a collet cap (fig. 1-1-94) and collet guide. The die halves are placed in the cap slot and are held in place by the guide which screws

Figure 1-1-93.—Types of adjustable dies.

11.5.2

9150

Figure 1-1-94.—Diestocks, diecollet, and tap wrenches.

11.5.6

44.31

Figure 1-1-95.—Adjustable die guide and ratchet diestocks.

into the underside of the cap. The die is adjusted by means of setscrews at both ends of the internal slot. This type of adjustable die is issued in various sizes to cover the cutting range of American Standard Coarse and Fine and special form threads. Diestocks to hold the dies come in three different sizes.

Two-piece rectangular pipe dies (fig. 1-1-93) are available to cut American Standard Pipe threads. They are held in ordinary or ratchet-type diestocks. (See fig. 1-1-95.) The jaws of the dies are adjusted by means of setscrews. An adjustable guide serves to keep the pipe in alinement with respect to the dies. The smooth

9151

jaws of the guide are adjusted by means of a cam plate; a thumbscrew locks the jaws firmly in the desired position.

Threading sets are available in many different combinations of taps and dies, together with diestocks, tap wrenches, guides and necessary screwdrivers and wrenches to loosen and tighten adjusting screws and bolts. Figure 1-1-96 illustrates typical threading set for pipe, bolts, and screws.

PIPE THREADING SET WITH RECTANGULAR ADJUSTABLE DIES, DIESTOCK, WRENCH, GUIDES AND TAPS

BOLT AND SCREW THREADING SET WITH ROUND ADJUSTABLE SPLIT DIES, DIESTOCKS, TAPS, TAP WRENCHES, AND SCREWDRIVERS

44.32

Figure 1-1-96.—A typical threading set.

Never attempt to sharpen taps or dies. Sharpening of taps and dies involves several highly precise cutting processes which involve the thread characteristics and chamfer. These sharpening procedures must be done by experienced personnel in order to maintain the accuracy and the cutting effectiveness of taps and dies.

Keep taps and dies clean and well oiled when not in use. Store them so that they do not contact each other or other tools. For long periods of storage, coat taps and dies with a rust-preventive compound, place in individual or standard threading set boxes, and store in a dry place.

THREAD CHASERS

Thread chasers are threading tools that have several teeth and are used to rethread damaged external or internal threads (chasing). (See fig. 1-1-97.) These tools are available to chase standard threads. The internal thread chaser has its cutting teeth located on a side face. The external thread chaser has its cutting teeth on the end of the shaft. The handle end of the tool shaft tapers to a point.

44.33

Figure 1-1-97.—Thread chasers.

SCREW AND TAP EXTRACTOR

Screw extractors are used to remove broken screws without damaging the surrounding material or the threaded hole. Tap extractors are used to remove broken taps.

Some screw extractors (fig. 1-1-98) are straight, having flutes from end to end. These extractors are available in sizes to remove broken screws having 1/4 to 1/2 inch outside diameters. Spiral tapered extractors are sized to remove screws and bolts from 3/16 inch to 2 1/8 inches outside diameter.

Most sets of extractors include twist drills and a drill guide. Tap extractors are similar to the screw extractors and are sized to remove taps ranging from 3/16 to 2 1/8 inches outside diameter.

Figure 1-1-98.—Screw and tap extractors.

VISES AND CLAMPS

Vises are used for holding work when it is being planed, sawed, drilled, shaped, sharpened, or riveted, or when wood is being glued. Clamps are used for holding work which because of its shape and size cannot be satisfactorily held in a vise, or when a vise is not available. Clamps are generally used for light work.

Figure 1-1-99 shows the most common bench vises that are used throughout the Navy.

A MACHINIST'S BENCH VISE is a large steel vise with rough jaws that prevent the work from slipping. Most of these vises have a swivel base with jaws that can be rotated, while others cannot be rotated. A similar light duty model is equipped with a cutoff. These vises are usually bolt-mounted onto a bench.

THE BENCH AND PIPE VISE has integral pipe jaws for holding pipe from 3/4 inch to 3 inches in diameter. The maximum working main jaw opening is usually 5 inches, with a jaw width of 4 to 5 inches. The base can be swiveled to any position and locked. These vises are equipped with an anvil and are also bolted onto a workbench.

The CLAMP BASE VISE usually has a smaller holding capacity than the machinist's or the bench and pipe vise and is usually clamped to the edge of a bench with a thumbscrew. These type vises can be obtained with a maximum holding capacity varying between 1 1/2 in. and 3 in. These vises normally do not have pipe holding jaws.

The BLACKSMITH'S VISE (fig. 1-1-100) is used for holding work that must be pounded with a heavy hammer. It is fastened to a sturdy workbench or wall, and the long leg is secured into a solid base on the floor.

The PIPE VISE (fig. 1-1-100) is specifically designed to hold round stock or pipe. The vise shown has a capacity of 1 to 3 inches. One jaw is hinged so that the work can be positioned and then the jaw brought down and locked. This vise is also used on a bench. Some pipe vises are designed to use a section of chain to hold down the work. Chain pipe vises range in size from 1/8- to 2 1/2 inch pipe capacity up to 1/2- to 8-inch pipe capacity.

A C-CLAMP (fig. 1-1-101) is shaped like the letter C. It consists of a steel frame threaded to receive an operating screw with a swivel head. It is made for light, medium, and heavy service in a variety of sizes.

A HAND SCREW CLAMP (fig. 1-1-101) consists of two hard maple jaws connected with two operating screws. Each jaw has two metal inserts into which the screws are threaded. The

Serg. 9153

Figure 1-1-99.—Common types of bench vises.

11.3(44)

hand screw clamp is also issued from supply in a variety of sizes.

CARE OF VISES AND CLAMPS

Keep vises clean at all times. They should be cleaned and wiped with light oil after using. Never strike a vise with a heavy object and never hold large work in a small vise, since these practices will cause the jaws to become sprung or otherwise damage the vise. Keep jaws in good condition and oil the screws and the slide frequently. Never oil the swivel base of swivel jaw joint; its holding power will be impaired. When the vise is not in use, bring the jaws lightly together or leave a very small gap and leave the handle in a vertical position.

Threads of C-clamps must be clean and free from rust. The swivel head must also be clean, smooth, and grit free. If the swivel head becomes damaged, replace it as follows: pry open the crimped portion of the head and remove the head from the ball end of the screw (fig. 1-1-102). Replace with a new head and crimp. For short storage, wipe down the clamps with a light coat of engine oil and then hang them on racks or pins, or carefully place them in a toolbox. For long storage, apply a rust-preventive compound to the C-clamp.

The screw of hand screw clamps may break or become damaged, the inserts may become worn, or the wooden jaws may split or warp. When it is necessary to replace any of these parts, disassemble the clamp (fig. 1-1-103). Remove handles from screws by filing off peened end of attaching pins. Drive out pins. Turn both screws from the inserts and remove the inserts from the jaws. Replace damaged screws, inserts and handles. Install inserts in jaws and turn the screws into position in the two jaws. Turn new screws into handle or old screw into new handle, depending on which part is being replaced. Aline holes and tap in a new pin. Peen end of pin to secure handle on screws. Keep screws lubricated with a few drops of light oil. Apply a light coat of linseed oil to wood surfaces to prevent them from drying out. If the finish of wooden jaws is worn and bare wood is exposed, coat jaws with varnish. Hang clamps on racks or pins, or carefully place them in a toolbox, to prevent damage when not in use. Wipe clean before storing.

11.3B

Figure 1-1-100.—Blacksmith's and pipe vises.

SAFETY PRECAUTIONS

When closing the jaw of a vise or clamp, avoid getting any portion of your hands or body between the jaws or between one jaw and the work.

When holding heavy work in a vise, place a block of wood under the work as a prop to prevent it from sliding down and falling on your foot.

Do not open the jaws of a vise beyond their capacity, as the movable jaw will drop off, causing personal injury and possible damage to the jaw.

SOLDERING IRONS

Soldering is joining two pieces of metal by adhesion. The soldering iron is the source of heat for melting solder and heating to the proper temperature the parts to be joined.

There are two general types of soldering irons in use by the Navy. They are the electrically heated and the nonelectrically heated. The essential parts of both types are the tip and the handle. The tip is made of copper.

The electric soldering iron (fig. 1-1-104) transmits heat to the copper tip after the heat is produced by electric current which flows through a self-contained coil of resistance wire, called the heating element. Electric soldering irons are rated according to the number of watts they consume when operated at the voltage stamped on the iron. There are two types of tips on electric irons: plug tips which slip into the heater head and, which are held in place by a setscrew, and screw tips which are threaded, and which screw into or on the heater head. Some tips are offset and have a 90-degree angle for soldering joints that are difficult to reach (not illustrated). A nonelectric soldering iron (fig. 1-1-104) is sized according to its weight. The commonly used sizes are the 1/4-, 1/2-, 3/4-, 1-, 1 1/2-, 2-, and 2 1/2-pound irons. The 3-, 4-, and 5-pound sizes are not used in ordinary work. Nonelectric irons have permanent tips and must be heated over an ordinary flame, or with a blowtorch.

Electric iron tips must be securely fastened in the heater unit. The tips must be clean and free of copper oxide. Sometimes the shaft oxidizes and causes the tip to stick in place. Remove the tip occasionally and scrape off the scale. If the shaft is clean, the tip will not only receive more heat from the heater element, but it will facilitate removal when the time comes to replace the tip. After use, hang soldering irons on a rack or place on a shelf. Do not throw irons into a toolbox. When storing irons for long periods of time, coat the shaft and all metal parts with rust-preventive compound and store in a dry place.

GRINDERS AND SHARPENING STONES

A hand bench grinder (fig. 1-1-105) is an axially mounted abrasive wheel with a handcrank

Figure 1-1-101.—C-Clamp and handscrew clamp.

Figure 1-1-102.—C-Clamp, exploded view.

that permits turning the wheel. The grinder is geared so that the wheel spins faster than the crank. This type grinder is clamped onto a bench and is equipped with a rest for alinement of the work when grinding.

The hand valve grinder (fig. 1-1-105) is used to lap engine valves to their seats. It consists of pinion gearing enclosed in a heavy machined cast iron housing. An external crank handle drives the gears, which rotate a shaft. The end of the shaft is designed to hold any one of three driving blades for use on slotted valves. Non-slotted valves can be driven by a rubber suction cup that is supplied with the grinder, that fits the shaft. Two shafts are furnished: one short and one long.

Keep grinders clean and make certain housing screws are tight. Periodically, drain oil from bench grinder and regrease valve grinder. Flush gear housings and gears with suitable cleaning solvent. Refill with manufacturer's recommended grade of lubricant. Remove rust from external surfaces with crocus cloth. After use, wipe clean and store in a suitable box or on a rack. Make certain all nuts, screws, and bolts are tight. For long periods of storage, lubricate and spread a rust-preventive compound on all metal parts. Wrap grinder in oil-soaked cloth and store in a dry place.

Sharpening stones are divided into two groups, natural and artificial. Some of the natural stones are oil treated during and after the manufacturing processes. The stones that are oil treated are sometimes called oilstones. Artificial stones are normally made of silicone carbide or aluminum oxide. Natural stones have very fine grains and are excellent for putting razorlike edges on fine cutting tools. Most sharpening stones have one coarse and one fine face. Some of these stones are mounted, and the working face of some of the sharpening stones is

9156

Figure 1-1-103.—Handscrew clamp, exploded view.

29.11C

a combination of coarse and fine grains. Stones are available in a variety of shapes, as shown in figure 1-1-106.

A fine cutting oil is generally used with most artificial sharpening stones, however, other lubricants such as kerosene may be used. When a tool has been sharpened on a grinder or grindstone, there is usually a wire edge or a feather edge left by the coarse wheel. The sharpening stones are used to hone this wire or feather edge off the cutting edge of the tool. Do not attempt to do a honing job with the wrong stone. Use a coarse stone to sharpen large and very dull or nicked tools. Use a medium grain stone to sharpen tools not requiring a finished edge, such as tools for working soft wood, cloth, leather, and rubber. Use a fine stone and an oilstone to sharpen and hone tools requiring a razorlike edge.

Prevent glazing of sharpening stones by applying a light oil during the use of the stone. Wipe the stone clean with wiping cloth or cotton waste after each use. If stone becomes glazed or gummed up, clean with aqueous ammonia or drycleaning solvent. If necessary, scour with aluminum oxide abrasive cloth or flint paper attached to a flat block.

At times, stones will become uneven from improper use. True the uneven surfaces on an old grinding wheel or on a grindstone. Another method of truing the surface is to lap it with a block of cast iron or other hard material covered with a waterproof abrasive paper, dipping the stone in water at regular intervals and continuing the lapping until the stone is true.

Stones must be carefully stored in boxes or on special racks when not in use. Never lay them down on uneven surfaces or place them where they may be knocked off a table or bench, or where heavy objects can fall on them. Do not store in a hot place.

PIPE AND TUBING CUTTERS AND FLARING TOOLS

Pipe cutters (fig. 1-1-107) are used to cut pipe made of steel, brass, copper, wrought iron, and lead. Tube cutters (fig. 1-1-107) are used to cut tubing made of iron, steel, brass, copper, and aluminum. The essential difference between pipe and tubing is that tubing has considerably thinner walls. Flaring tools (fig. 1-1-108) are used to make single or double flares in the ends of tubing.

Two sizes of hand pipe cutters are generally used in the Navy. The No. 1 pipe cutter has a cutting capacity of 1/8 to 2 inches, and the No. 2 pipe cutter has a cutting capacity of 2 to 4 inches.

Figure 1-1-104.—Soldering irons.

11.145:1.26

The pipe cutter (fig. 1-1-107) has a special alloy-steel cutting wheel and two pressure rollers which are adjusted and tightened by turning the handle.

Most TUBE CUTTERS closely resemble pipe cutters, except that they are of lighter construction. A hand screw feed tubing cutter of 1/8-inch to 1 1/4-inch capacity (fig. 1-1-107) has two rollers with cutouts located off center so that cracked flares may be held in them and cut off without waste of tubing. It also has a retractable cutter blade that is adjusted by turning a knob. Other types of tube cutters shown are designed to cut tubing up to and including 3/4 and 1 inch outside diameter. Some cutters have the feed screw covered to protect the threads against dirt and damage.

FLARING TOOLS (fig. 1-1-108) are used to flare soft copper, brass, or aluminum to make 45° flare joints. The single flaring tool consists of a split die block that has holes for 3/16-, 1/4-, 5/16-, 3/8-, 7/16-, and 1/2- inch o.d. tubing, a clamp to lock the tube in the die block, and a yoke that slips over the die block and has a compressor screw and a cone that forms a 45° flare or a bell shape on the end of the tube. The screw has a T-handle. A double flaring tool has the additional feature of adapters that turn in the edge of the tube before a regular 45° double flare is made. It consists of a die block with holes for 3/16-, 1/4-, 5/16-, 3/8-, and 1/2-inch tubing, a yoke with a screw and a flaring cone, plus five adapters for different size tubing, all carried in a metal case.

9158

MISCELLANEOUS TOOLS

Tools described under the heading "miscellaneous tools" are tools that cannot properly be listed under such headings as "metal-cutting tools" or "woodworking tools." Instead, they are tools that are likely to be used by all men in the Navy sometime during their careers.

The miscellaneous tools are not likely to be found in any particular toolkit, but will be stored in a central toolroom to be checked out when they are needed. You will find many of these tools mentioned several times throughout the text. This section will give you some tips on nomenclature, where the tools can be used, how they are used, and some safety precautions to be observed when using the tools.

Figure 1-1-105.—Hand grinders.

ADZ

The adz (fig. 1-1-109) consists of a hardened steel head which has a square eye at the top and a curved blade at one end. The blade is 3 1/2 to 4 1/2 inches wide. It has a wooden handle, which is curved to give balance and to provide the proper angle for cutting.

The adz is used for cutting, shaping, and smoothing of logs when a large amount of wood is to be removed.

Securely block the timber which is to be worked on, to prevent it from slipping, sliding, or rolling. Keep the area being cut clear of chips, because they may deflect the blade and cause it to injure your foot or leg.

To use the adz, the timber to be worked on should be straddled. Grip the handle of the adz with the hands about 12 to 15 inches apart with the tool in front of the body. Make short, chopping strokes by swinging the adz downward and toward the body.

The head of the adz must be removed from the handle for sharpening. Remove the nicks from the edge of the blade by moving the edge back and forth across the wheel of a grindstone.

Figure 1-1-106.—Shapes of sharpening stones and oilstones.

9159

Figure 1-1-107.—Pipe and tubing cutters. 44.36

Then restore the bevel edge to its original shape. Keep the edge square (at a right angle) with the head.

Inspect the handle of the adz frequently for split or broken wood. To insert the handle, seat it into the eye of the head by striking the opposite end of the handle with a mallet.

When not in use, place the adz on its head with the handle standing upward, or hang the adz in a rack. After use, clean the adz head and coat it with light oil before putting it away.

AX

The ax is used to fell or to prune trees, to cut logs and brush, and to split and cut wood. It can also be used for cutting and shaping logs for columns and cribs. Axes are used by fireman and damage control teams to gain entrance into compartments or buildings during a disaster.

In using the ax (fig. 1-1-110), the body weight should be distributed evenly on both legs, with the knees set but not tense, and the feet spread apart at a comfortable distance. The body should be relaxed and free to swing and bend from the hips. The ax may be used with either hand leading, and both positions should be used to prevent tiring provided, of course, you have the ability to swing right-handed or left-handed. With the right hand leading, the left foot should be brought slightly toward the work. The handle is held at the end by the left hand and near the center by the right hand. The ax is then brought up over the shoulder. As it is swung forward, the right hand slides back along the handle toward the left hand so that at the finish of the swing the hands are close together. With the left hand leading on the ax handle, the ax is swung in the same manner, except the positions are reversed.

44.37

Figure 1-1-108.—Flaring tools.

44.39

Figure 1-1-109.—The adz.

Before swinging an ax, make sure no one is in the way of your swing. Clear away any branches, twigs, or other obstruction that might tend to deflect the blade from the target. Keep the blade sharp. A dull blade may be deflected and injure the foot or leg. Keep the blade clear of chips which may deflect the blade. If you are using an ax to cut used timbers make sure that all nails have been removed from the area that is being cut.

It is not necessary to remove the ax handle for sharpening the ax blade. (See fig. 1-1-111.) First remove nicks by moving the edge of the blade back and forth across a grindstone. Then restore the bevel by holding first one side then the other against the stone. The ax bevel should be slightly convex, or "rolled off." The edge is slightly curved, or fan-shaped, instead of straight across the head of the blade.

When grinding an ax, a wet grindstone should be used. Dip the ax in water frequently to keep it from overheating. Start to grind 2 or 3 inches back from the cutting edge and grind to within about 1/2 inch from the edge. Using a hone or whetstone, sharpen the remaining 1/2 inch and remove all scratches from the area which has been ground. A scratch left on highly tempered steel can cause it to break where it is scratched.

After an ax is used, it should be cleaned, sharpened, and coated with a light film of oil. Store it in a place where it will not fall and injure anyone and so as not to damage the sharp edge.

HATCHET

The half-hatchet, commonly called hatchet, is a chopping and driving tool similar in some respects to a hammer. It is used for light cutting, trimming, and hewing, and (because it is heavier than a hammer) for driving large nails and spikes. (See fig. 1-1-112.) It has a wooden handle and a steel head composed of a hammerhead, and eye, and a blade. Some hatchets have a notch in the blade for pulling nails. Hatchets

9161

Figure 1-1-110.—Using the Ax.

Figure 1-1-111.—Sharpening the Ax.

44.41

Figure 1-1-112.—Half-hatchet.

are made with two types of cutting edge (fig. 1-1-112): the single bevel and the double bevel. The double bevel is the more common. The single bevel hatchet is ideal for cutting to a line.

To make heavy strokes with the hatchet, grasp the handle with one hand near its end; for light strokes, hold the handle close to the head. The hatchet is used principally to hew to a line with the grain of the wood. To do so, set the wood being hewn on edge and make a series of small, closely spaced cuts at an angle of about 45 degrees across the grain and near the line. Cut away the notched segments by striking with the grain along the line. In making the scoring cuts, when the grain is irregular, change the direction of the blow to cut across the grain with every stroke.

The care, the maintenance, and the safety rules to be followed when using a hatchet are the same as previously described for the ax.

MASONRY DRILLS

Masonry drills (fig. 1-1-113) frequently called star drills, are shafts of steel with a cutter at one end and a flat face on the other.

282-344 O - 67- 5

0163

Figure 1-1-113.—Masonry drill. 44.42

44.43

Figure 1-1-114.—Brick trowel.

Looking at the drill from the end, the cutter resembles four chisels fastened together at their edges. Masonry drills are made in various sizes up to 1 3/4 inches in diameter and 18 to 48 inches in length.

The masonry drill is used for drilling holes in concrete or stone. The cutter end is placed where the hole is to be drilled and the head of the drill is struck with a heavy hammer or sledge. The drill must be rotated after each blow to clear the drilled material from the hole and to keep the drill from binding. In hard stone it is useful to keep the hole wet, both to help clear the hole of drilled material and to keep the drill cool.

The cutting edges are sharpened by grinding on a grinding wheel or by filing, taking care to maintain the original bevel on both sides of the cutting edges. The head of the drill may become burred or broken from the blows from the hammer; it can be restored by grinding or filing.

Always wear goggles when using the masonry drill. Bits of rock or concrete, and rock or concrete dust, will sometimes fly from the material being drilled and may injure your eyes if they are not protected. Keeping the hole wet will lessen the amount of dust raised. Because the drill and the hammer or sledge are both of steel, bits of this material may be broken off from the head of the drill and cause injury.

When holding a masonry drill for another person to strike with a sledge or hammer, always stand at one side of his swing, instead of directly in front of him. This will lessen the danger of injury should the hammer or sledge slip from his grasp or the head of the hammer or sledge come loose.

TROWELS

The BRICK trowel (fig. 1-1-114) is a pointed steel blade about 5 inches wide at the heel and 10 inches long. At the wide end, a wooden handle is fastened to the blade by means of a tang. The tang is bent upward slightly, so that the handle is slightly above the blade in use.

The blade of the trowel is used to scoop and spread mortar, and to chip and cut bricks. The end of the handle is used to tap bricks into place.

Scoop and carry the mortar on the wide part of the blade. This keeps the weight close to the wrist and avoids tiring the hand and wrist. Dump the mortar from the side of the trowel with a quick, chopping motion. Spread it into position with the point of the trowel. With the edge of the trowel cut off any surplus mortar coming out of the joint.

If a beveled or V-shaped joint between the bricks is desired, draw the point of the trowel along the joint, thus forcing the mortar into the joint. The edge of the trowel may be used to chip hardened bits of mortar or other material from the surface of the bricks. To cut a brick with a trowel, strike it sharply with the edge of the trowel at the point where you wish the brick to be cut.

In chipping brick, goggles should be worn to prevent chips or dust from getting into the eyes. If goggles are not available, hold the brick to be cut well away from the face. Do not hold the brick with your hand close to where the cut is being made. You may chop your finger instead of the brick.

The CEMENT trowel (fig. 1-1-115) is a flat rectangular blade about 4 inches wide and 14 inches long. A wooden handle is fastened to the back of the blade in its middle by means of a metal tang and strap.

The cement trowel is used for finishing concrete surfaces. While the concrete is still wet, it may be pushed into place and uneven spots leveled by moving the cement with the edge of the trowel.

To get a smooth surface on the concrete, wait until the concrete has partly set. Then dip the trowel in water and use it much as you would use a flat iron in ironing clothes to smooth out all

9164

Figure 1-1-115.—Cement trowel. 29.164A

coarse appearing parts of the surface, taking care that the edge of the trowel does not gouge into the surface. The trowel must be kept wet by dipping it into water. Additional water can be brought to the surface of the concrete by slapping the surface with the flat of the trowel while finishing.

Clean all mortar from the trowel, including the handle, by washing it in water after use. If mortar hardens on the blade the trowel becomes useless until it is chipped or cleaned off. Mortar left to harden on the handle will scratch the hands when the trowel is next used. Oil the trowel lightly after it is used and before it is put away.

After working with mortar or cement, wash all cement dust from the skin and remove dirty clothing. The lime in the mortar or cement may burn the skin.

PICKS

The pick (fig. 1-1-116) is a tool that is designed for digging in hard earth. It consists of a steel head set on a wooden handle, which is inserted through an eye in the middle of the head. One end of the head tapers to a sharp point; the other end is chisel shaped.

The pick is used for loosening hard clay or rocky earth so that it may be removed with a shovel. A small amount of prying may be done with a pick; for heavy prying, a bar should be used.

Do not use a pick in extremely cold weather without first warming the head. Steel becomes brittle in extreme cold, and the head may be broken if used for very heavy blows while it is cold. To sharpen the pick, the head should be removed from the handle. The pick is then sharpened on a grinding machine in the same way as an ax. In the field, where a grinding machine is not available, a coarse file may be used to sharpen the points of a pick.

Observe the same safety precautions when using a pick as you do when using an ax.

SHOVELS

The shovel is a steel blade set on a wooden handle, and is used for moving earth or other material. The blades of some shovels are slightly pointed for easier cutting of earth and the back of the blade is cut off square so that the foot may be used to force the tool into the ground.

There are many types of shovels for various uses. The types generally found in the Navy are the D-handled round point and the long-handled round point (fig. 1-1-117).

The D-handled round point shovel is designed for light work or for digging in cramped spaces. It has a short handle (about 3 feet in length), at

Figure 1-1-116.—Pick. 44.44

29.234A

Figure 1-1-117.—Types of shovels commonly used in the Navy.

the top of which is a D-shaped metal strap, into which is set a short wooden crosspiece for a hand grip.

The long-handled round point shovel is the best for most kinds of heavy work, such as digging trenches or any other digging in which there is sufficient room to swing it. This shovel has no hand grip. Instead the handle is a long (about 5 feet), round pole.

Shovels should not be used for heavy prying; this may break the handle or bend the blade. After use, shovels should be cleaned and oiled. To sharpen the blade after it has been worn, first hammer it into proper shape on a piece of hard wood or an anvil. Then file the point.

To replace the handle on a shovel, cut or grind off the heads of the rivets which hold the blade to the handle. Drive out the rivets and pull the handle from the socket. Insert a new handle and drill rivet holes through it. Drive in and peen the new rivets. If the handle has been broken off close to the socket, it may be necessary to bore the handle out of the socket.

When using a shovel, be sure your working space is free, so that you will not injure another worker when you swing the shovel. Try to throw the material where it will not have to be moved a second time and where it will do no harm.

PINCHBAR

The pinchbar is a steel rod, usually made of 3/4-inch bar stock, with one pointed end and one chisel, or wedge-shaped end. The wedge end is set at a slight angle to the bar. (See fig. 1-1-118A.) The pinchbar is generally used for prying, such as in opening boxes and crates and in loosening boards.

WRECKING BARS

Wrecking bars may be either straight "claw and pinchpoint" or "goosenecked." In any case, the wrecking bar has a claw at one end. The other end is wedge chisel shaped, and bent at a slight angle to the bar (fig. 1-1-118B).

Figure 1-1-118.—Bars.

The wrecking bar is used for prying boards loose and for removing large nails or spikes from boards. The wedge-shaped end is inserted between boards to be removed, and the boards pried loose by exerting leverage on the other end of the bar. The claw is used in the same manner as is the claw on a claw hammer.

The gooseneck bar is usually of lighter weight than the straight wrecking bar. Large spikes should be drawn with the straight bar instead of with the gooseneck, as the lighter gooseneck bar may be bent out of shape in trying to draw too heavy a spike.

CROWBAR

The crowbar is a heavy steel bar about 5 feet in length. One end is square in cross section, and has a wedge-shaped point. The rest of the bar is round and forms the handle (fig. 1-1-118C).

The crowbar is used as a lever for moving heavy objects short distances. It is also used for prying loose heavy boulders and for breaking up hard earth formations in digging. It is a sturdy tool, designed for heavy and hard usage.

9166

PART I

Section 2

COMMON POWER TOOLS

Power tools can be either electrically or pneumatically powered and are hand-operated. They are becoming so commonplace in the Navy that men in nearly all ratings will have a need to use some power tools at one time or another. This section of Basic Handtools will acquaint you with the more common types of power tools and equipment. It will also discuss safety precautions, general operating practices, and the necessary care and maintenance of your machines.

Safety cannot be overemphasized when discussing power tools. There are several general rules that will help guide you. Before using a power tool or piece of equipment, remove all loose tools or other objects from it, and make all necessary adjustments. Use only sharp-edged cutting tools, since dull tools are safety hazards.

While operating a power tool, give it full attention. Keep all safety guards in position, and use safety shields or goggles when necessary. Fasten all loose sleeves, neckties, and aprons. Do not disturb or in any way distract another man while he is operating a power tool.

After using a power tool, turn off the power, and clean the tool. Remove all waste and scraps from the deck around it.

PORTABLE ELECTRIC POWER TOOLS

Portable electric power tools are tools that can be easily moved from place to place with a minimum of effort. These are probably the most used of all power tools. Some of the most common portable electric power tools that you will use in the Navy are drills, hammers, sanders, grinders and saws.

When using any electric power tool make sure the source of power is of the correct voltage. If an electric tool is designed to operate on 115 volts never plug it into any other power source. The switch on the tool must be in the "OFF" position before it is plugged in. Make sure the cord and plug are in good condition and that the tool is properly grounded before using it. Check appendix III for detailed instructions on grounding.

DRILLS

The portable electric drill is probably the most frequently used portable power tool in the Navy. It is especially designed for drilling holes in wood or metal with speed and ease. But today the electric drill has practically developed into a motorized shop that you can hold in one hand. There are so many different types of electric drills with so many diversified accessories that you can add, that they can be used for many different jobs. Sanding, sawing, buffing, polishing, screw-driving, wire brushing, paint mixing—these are samples of possible uses.

Portable electric drills commonly used in the Navy have capacities for drilling holes in steel from 1/16 inch up to 1 inch in diameter. The sizes of portable electric drills are classified by the maximum size straight shank drill it will hold. That is, a 1/4 inch electric drill will hold a straight shank drill up to and including 1/4 inch.

Figure 1-2-1 shows two popular types of spade handle electric drills. The handles may also be in the shape of a pistol grip. Some of the heavy duty type drills have a provision for an additional projecting bar which can be mounted for applying added feed pressure. Most important when choosing a drill for a job are the revolutions per minute (rpms) and power it will deliver. You will find that the speed of the drill motor decreases with an increase in size, primarily because the larger units are designed to turn larger cutting tools or to drill in heavy

9167

1.25.2

Figure 1-2-1.—Portable electric drills.

materials, and both these factors rule for slower speed.

If you are going to do heavy work, such as drilling in masonry or steel, then you would probably need to use a drill with a capacity of 3/8 inch or 1/2 inch. If most of your drilling will be forming holes in wood or small holes in sheet metal, then a 1/4-inch drill will probably be adequate.

The chuck is the clamping device into which the drill is inserted. Nearly all electric drills are equipped with a three-jaw chuck. Some of the drill motors have a hand-type chuck that you tighten or loosen by hand but most of the drills used in the Navy have gear-type, three-jaw chucks which are tightened and loosened by means of a chuck key, shown in figure 1-2-2. Never leave the chuck key in the chuck at any time. Always remove the key IMMEDIATELY after you use it. Otherwise the key will fly loose when the drill motor is started and may cause serious injury to you or one of your shipmates. The chuck key is generally taped on the cord of the drill; but if it is not, make sure you put it in a safe place where it will not get lost.

44.46

Figure 1-2-2.—Three jaw chuck and chuck key.

All electric drills used in the Navy have some sort of a system for grounding. Make sure that the ground connection is properly made before turning on the drill motor. Proper grounding will prevent injury to you in the event that the internal wiring becomes shorted to the motor housing. Figure 1-2-3 shows one type of ground connection, however, a three prong plug and receptacle should be used when available.

If you must use a portable electric drill at some distance from the source of power make sure you use an extension cord of proper size to prevent excessive voltage drop. You can check with the electricians in the electric shop for this information.

44.47

Figure 1-2-3.—Proper grounding of portable electric tool.

All portable electric drills used in the Navy have controls similar to the ones shown on the 1/4-inch drill in figure 1-2-4. This drill has a double pole momentary contact trigger switch located in the pistol grip handle. The switch trigger is squeezed to start the electric drill and released to stop it.

The trigger latch is a button in the bottom of the drill handle. It is pushed in, while the switch trigger is held down, to lock the trigger switch in the "ON" position. The trigger latch is released by squeezing and then releasing the switch trigger.

SANDERS

Portable sanders are tools designed to hold and operate abrasives for sanding wood, plastics and metals. Power sanders have made the finishing of wood and metal surfaces easy and fast. Power sanders are widely used in the Navy to

4.35A

Figure 1-2-4.—1/4-inch portable electric drill.

prepare surfaces for paint. The most common types found in the Navy are the DISK sander, BELT sander and RECIPROCATING ORBITAL sander.

The safety precautions to be observed while operating electric sanders are much the same as for the portable electric drill. That is, make sure the tool is properly grounded and in good operating condition prior to operation.

Safety goggles must be worn when operating any tool where dust and flying particles are produced. When sanding some materials, for example, reinforced plastics, respiratory precautions must be observed.

Disk Sander

The disk sander (fig. 1-2-5) is much like a portable drill with an abrasive disk attached. It has a straight type rear grip and a detachable side handle. The straight type rear handle has a slide button switch located on top. The disk sanders come in many different sizes but the most common ones found in the Navy will accommodate a 6- or 7-inch sanding pad.

44.49

Figure 1-2-5.—Portable electric sander

Electric disk sanders are especially useful on work where a large amount of material is to

9169

Figure 1-2-7.—Orbital sander.

44.50

Figure 1-2-8.—Portable grinder.

44.51

either AC or DC current which makes it adaptable to use on either shore stations or aboard ship.

The nameplate for the portable grinder is attached to the top of the motor housing. It contains the following data: manufacturer's name and address, model number, no-load rpm, serial number, AC cycles per second, amperage, number of AC phases, voltage, type of current required, and a warning concerning the need for grounding the grinder when in use.

There is a flexible shaft attachment that is available for most portable grinders. This shaft is attached by removing the grinding wheel then attaching the shaft to the grinding wheel drive spindle. The grinding wheel can then be attached to the end of the flexible shaft. This attachment is invaluable for grinding surfaces in hard to reach places.

It is particularly important that the ground conductor be connected to ground when there is presence of water in the work area. This will prevent possible injury to you in the event that the internal wiring of the grinder becomes shorted to the field case.

The wheel guard on the grinder should be positioned so that abrasive dust and metal particles will be deflected away from your face.

Before you turn the grinder on, make sure the abrasive grinding wheel is properly secured to the grinder spindle and not cracked or damaged.

29.133

Figure 1-2-9.—Portable electric circular saw.

PORTABLE CIRCULAR SAW

The portable circular saw, often called Skilsaw, is one of the most used power machines by people who have occasion to work with wood. They are becoming more and more popular because of the time and labor they save, the precision with which they work, and their ease of handling and maneuverability.

Because of the many types of portable circular saws in the Navy supply system, and the changes being made in the design of these saws, only general information will be given in this section. Information concerning a particular saw can be found by checking the manufacturer's manual.

The sizes of portable electric saws range from one-sixth horsepower with a 4-inch blade to one-and-one half horsepower with a 14-inch blade. They are so constructed that they may be used as a carpenter's handsaw, both at the job site or on a bench in the woodworking shop.

The portable electric saw (fig. 1-2-9) is started by pressing a trigger inserted in the handle and stopped by releasing it. The saw will run only when the trigger is held.

Most saws may be adjusted for crosscutting or for ripping. The rip saw guide is shown at (A, fig. 1-2-9). In this illustration it is turned up out of the way since the saw is being used as a crosscut saw. A guideline for crosscutting may be marked across the board as at B or the crosscut guide (F, fig. 1-2-9) may be used. When one straight side of this guide is held against the edge of the board, the other straight side will be at a right angle to this edge. The base plate of the saw can then slide along this guide and the saw will produce a square cut.

The depth of the cut is regulated by the adjusting thumbscrew shown at C. The adjustment for angle cutting is shown at D. This permits the base to be tilted in relation to the saw. A rapid adjustment may be made by the use of the graduated scale marked in degrees on the quadrant (E).

The bottom plate of the saw is wide enough to provide the saw with a firm support on the lumber being cut. The blade of the saw is protected by a spring guard which opens when lumber is being cut but snaps back into place when the cut is finished. Many different saw blades may be placed on the machine for special kinds of sawing. By changing blades almost any building material from slate and corrugated metal sheets to fiberglass can be cut.

Most portable electric saws are equipped with universal motors that will operate on either AC or DC current and require 115 volts. As with other portable electric tools, they must be grounded before they are turned on.

9172 1718

The portable electric saw is one of the most dangerous power tools in existence when it is not properly used. Make sure the board you are sawing is properly secured so it will not slip or turn. After making a cut be sure the saw blade has come to a standstill before laying the saw down.

When using an electric saw remember that all the blade you can normally see is covered; the portion of the blade that projects under the board being cut is not covered. The exposed teeth under the work are dangerous and can cause serious injury if any part of your body should come into contact with them.

Make sure the blade of a portable circular saw is kept sharp at all times. The saw blade will function most efficiently when the rate of feed matches the blade's capacity to cut. You will not have to figure this out—you will be able to feel it. With a little practice you will know when the cut is smooth and you will know when you are forcing it. Let the blade do its own cutting. The tool will last longer and you will work easier because it is less fatiguing.

SABER SAW

The saber saw (fig. 1-2-10) is a power driven jigsaw that will let you cut smooth and decorative curves in wood and light metal. Most saber saws are light duty machines and are not designed for extremely fast cutting. About the same safety precautions must be observed when using the saber saw as for any other portable power tool.

There are several different blades designed to operate in the saber saw and they are easily interchangeable. For fast cutting of wood, a blade with coarse teeth may be used. A blade with fine teeth is designed for cutting metal.

The best way to learn how to handle this type of tool is to use it. Before trying to do a finished job with the saber saw, clamp down a piece of scrap plywood and draw some lines to follow, curved ones as well as straight ones. You will develop your own way of gripping the tool, and this will be affected somewhat by the particular tool you are using. On some tools, for example, you will find guiding easier if you apply some downward pressure on the tool as you move it forward. If you are not firm with your grip, the tool will tend to vibrate excessively and this will roughen the cut. Do not force the cutting faster than the design of the blade allows or you will break the blade. If this happens do not blame the tool.

ELECTRIC IMPACT WRENCH

The electric impact wrench (fig. 1-2-11) is a portable hand-type reversible wrench. The one shown has a 1/2-inch square impact driving anvil over which 1/2-inch square drive sockets can be fitted. Wrenches also can be obtained that have impact driving anvils ranging from 3/8

Figure 1-2-10.—Portable electric saber saw.

44.52

Figure 1-2-11.—Reversible electric impact wrench.

44.53

inch to 1 inch. The driving anvils are not interchangeable, however, from one wrench to another. The reversing ring, located on the rear of the motor housing, is held in place by a brush holder cover.

A pistol-grip handle, which contains the on-and-off trigger switch, is an integral part of the motor housing. The wrench is equipped with a three-cable flexible cord having a male contact plug connector and one ground cable.

The electric wrench with its accompanying equipment (fig. 1-2-12) is primarily intended for applying and removing nuts, bolts, and screws. It may also be used to drill and tap metal, wood, plastics, etc., and drive and remove socket-head, Phillips-head, or slotted-head wood, machine, or self-tapping screws.

When you use an electric wrench that you are not completely familiar with, first check the voltage specifications and make sure the source of power is correct. After connecting the wrench to a suitable power source, depress the on-and-off trigger switch and allow the electric wrench to operate a few seconds, noting carefully the direction of rotation. Release the trigger switch to stop the wrench. Turn the reversing ring located at the rear of the tool; it should move easily in one direction (which is determined by the current direction of rotation). Depress the on-and-off trigger again to start the electric wrench. The direction of rotation should now be reversed. Continue to operate for a few seconds in each direction to be sure that the wrench and its reversible features are functioning correctly. When you are sure the wrench operates properly, place the suitable equipment on the impact driving anvil and go ahead with the job at hand.

SOLDERING GUNS

The soldering gun (fig. 1-2-13) is an induction-type soldering iron. This is not mechanical in the sense that it does not have any moving parts, but is becoming widely used throughout the Navy by men in nearly every rating.

The soldering gun operates on any standard electrical outlet and is rated in size by the number of watts it produces. The guns used

9175

Figure 1-2-13.—Electric soldering gun.

in the Navy are rated between 100 and 250 watts. All good quality soldering guns operate in a temperature range of 500 to 600° F. The important difference in gun sizes is not the temperature, but the capacity of the gun to generate and maintain a satisfactory soldering temperature while giving up heat to the joint soldered.

Soldering guns contain a stepdown transformer in their bodies. The transformer secondary output current flows through the tip, causing it to heat. The tip heats only when the trigger is depressed, and then very rapidly. These guns afford easy access to cramped quarters, because of their small tip. Most soldering guns have a small light that is focused on the tip working area.

To prevent damage to the soldering gun, never subject it to heavy mechanical abuse. For instance, if the gun is dropped, or used as a hammer or a pry, the heating element may be broken or shorted or the tip may become bent. Always make certain that the cord does not come in contact with the tip where it can be burned.

The tip of a soldering gun should be removed occasionally to permit cleaning away the oxide scale which forms between the tip and metal housing. Removal of this oxide increases the heating efficiency of the gun. If for any reason the tip does become damaged, replaceable tips are available.

PORTABLE PNEUMATIC POWER TOOLS

Portable pneumatic power tools are tools that look much the same as electric power tools but are powered by compressed air instead of electricity. Because of the limited outlets for compressed air aboard ship and shore stations, the use of pneumatic power tools is not as widespread as electric tools. Portable pneumatic tools are used most around a shop where compressed air outlets are more readily accessible.

PORTABLE PNEUMATIC DRILL

Portable pneumatic drills are made in several different sizes, however, those most commonly used in the Navy will accommodate 1/2-inch drills for metal drilling and up to 1-inch drills for wood boring. (See fig. 1-2-14.) The pneumatic drills are intended for drilling or enlarging holes in metal, wood, plastics, etc.

Most pneumatic drills consist of a cast aluminum housing with a pistol-grip handle. There is a built-in air reservoir, a centrifugally actuated governor, a removable air strainer, a reduction gear case, and a rotor having a splined shaft mounted on ball bearings.

For proper operation, pneumatic drills require air pressure from 70 to 90 psi. Check the specifications on the drill you have and make sure you have the proper air pressure.

The air motor requires clean air and lubrication. Care should be taken to ensure clean couplings and air hose. In extremely dusty, humid, and cold regions, air compressor air filters and/or moisture traps are required to ensure that compressed air is dry and free from foreign matter. You should make sure that the air filters and moisture traps are cleaned periodically as suggested by the manufacturer's manual.

The only control required for operation of the pneumatic drill is the trigger (fig. 1-2-15). To start the drill the trigger is depressed. When the trigger is fully depressed it locks in the "ON" position. To release the locked trigger, the button end (left side of the pistol-grip handle) of the lock pin is depressed. The trigger will be released and will return to the "OFF" position.

Before operating a pneumatic drill inspect the air hose and check for any leaks and damage. Blow air through the air hose to free it of foreign material before connecting it to the

Figure 1-2-14.—Portable pneumatic drill.

Figure 1-2-15.—Controls of a pneumatic drill. 1.25.2B

drill. Keep air hose clean and free from lubricants.

Make certain the tool being used in the chuck is properly secured and check the operation of the trigger to make sure it is working properly. Check the pneumatic drill for evidence of exterior damage. Tighten all loose fittings, nuts and bolts. Make sure the drill motor has been properly lubricated in accordance with the manufacturer's specifications.

PNEUMATIC CHIPPING HAMMER

The pneumatic chipping hammer (fig. 1-2-16) consists basically of a steel piston which is reciprocated (moved backward and forward

9177

Figure 1-2-16.—Pneumatic chipping hammer.

alternately) in a steel barrel by compressed air. On its forward stroke the piston strikes the end of the chisel, which is a sliding fit in a hexagon nozzle pressed into the barrel. The rearward stroke is cushioned by compressed air to prevent any metal-to-metal contact. Reciprocation of the piston is automatically controlled by a valve box assembly located on the rear end of the barrel. Located on the rear end of the barrel is a grip handle, containing a poppet-type throttle valve.

The throttle valve is actuated by a throttle lever which protrudes from the upper rear of the grip handle for thumb operation. Projecting from the butt of the handle is an air inlet. The handle is threaded onto the barrel and is prevented from unscrewing by a locking ring. Surrounding and retaining the locking ring is an exhaust deflector. This deflector may be located in any of four positions around the barrel in order to throw the stream of exhaust air in the desired direction.

The pneumatic hammer may be used for beveling, calking or beading operations, and for drilling in brick, concrete, and other masonry. The chipping hammer is especially useful for preparing metal surfaces for painting.

Chipping hammers should not be operated without safety goggles and all other persons in the immediate vicinity of the work should wear goggles.

While working never point the chipping hammer in such a direction that other personnel might be struck by an accidentally ejected tool. When chipping alloy steel or doing other heavy work, it is helpful to dip the tool in engine lubricating oil about every 6 inches of the cut and make sure the cutting edge of the tool is sharp and clean. This will allow faster and easier cutting and will reduce the possibility of the tool breaking.

When nearing the end of a cut, ease off on the throttle lever to reduce the intensity of the blows. This will avoid any possibility of the chip or tool flying.

If for any reason you have to lay the chipping hammer down, always remove the tool from the nozzle. Should the chipping hammer be accidentally started when the tool is free, the blow of the piston will drive the tool out of the nozzle with great force and may damage equipment or injure personnel.

PORTABLE PNEUMATIC IMPACT WRENCH

The portable pneumatic impact wrench (fig. 1-2-17) is designed for installing or removing

Figure 1-2-17.—Portable pneumatic impact wrench. 44.56

nuts and bolts. The wrench comes in different sizes and is classified by the size of the square anvil on the drive end. The anvil is equipped with a socket lock which provides positive locking of the socket wrenches or attachments. The wrench has a built-in oil reservoir and an adjustable air valve regulator which adjusts the torque output of the wrench. The torque regulator reduces the possibility of shearing or damaging threads when installing nuts and bolts to their required tension.

Nearly all pneumatic wrenches operate most efficiently on an air pressure range of 80 to 90 psi. A variation of plus or minus 5 pounds is serious. Lower pressure causes a decrease in the driving speeds while higher pressure causes the wrench to overspeed with subsequent abnormal wear of the motor impact mechanisms.

The throttle lever located at the rear of the pneumatic wrench provides the means for starting and stopping the wrench. Depressing the throttle lever starts the wrench in operation. Upon release, the lever raises to its original position stopping the wrench.

The valve stem is seated beneath the pivot end of the throttle lever. Most wrenches have a window cut in the throttle lever so that the markings on the upper surface of the valve stem will be visible. Two letters, "F" and "R," have been engraved on the head of the valve stem to indicate the forward (clockwise) and reverse (counterclockwise) rotation of the anvil. To change from forward to reverse rotation, or vice versa, turn the valve stem 180° until the desired marking is visible through the window in the throttle lever. When the valve stem is in proper position, the valve stem pin engages a recess on the under side of the valve stem, preventing accidental turning of the stem.

The air valve regulator is located at the bottom and towards the rear of the wrench. Using a screwdriver and altering the setting of the air regulator up to 90°, either to the right or left, reduces the torque from full power to zero power.

282-344 O - 67 - 6

9179

8180

Before operating the pneumatic impact wrench make sure the socket or other attachment you are using is properly secured to the anvil. It is always a good idea to operate the wrench free of load in both forward and reverse directions to see that it operates properly. Check the installation of the air hose to make sure it is in accordance with the manufacturer's recommendation.

COMMON POWER MACHINE TOOLS

Small power machine tools are, generally speaking, not portable. All work that is to be done must be brought to the shop where the machine is set up. Only the most common types of power machine tools will be discussed in this text. There are many power machine tools used by people of specific ratings but most of them require a degree of skill that can be learned only by working with them.

The tools that will be discussed here are tools that may be found in several shops aboard ship or on shore stations. They are tools that are not confined to operation by men of any one particular rating but may be used by men of several ratings.

DRILL PRESS

The drill press is an electrically operated power machine that was originally designed as a metal-working tool. As such its applications would be limited in the average shop. Available accessories, plus jigs and special techniques, now make it a versatile wood-working tool as well.

There are two basic types of drill presses used in the Navy. They are the bench-type drill press (fig. 1-2-18) and the upright-type drill press (fig. 1-2-19). These two types drill presses are basically the same, the difference being in the mounting. As the names suggest, the bench-type drill press is mounted on a work bench and the upright-type drill press is mounted on a pedestal on the floor.

Drill presses are manufactured in a number of sizes, however, only the small size drill press will be discussed in this text. The drill presses most commonly found in shops in the Navy have a capacity to drill holes in metal up to 1 inch in diameter. The driving motors range in size from 1/3 hp to 3 hp.

The motor is mounted to a bracket at the rear of the head assembly and designed to permit V-belt changing for desired spindle speed without removing the motor from its mounting bracket. Four spindle speeds are obtained by locating the V-belt on any one of the four steps of the spindle-driven and motor-drive pulleys.

44.59

Figure 1-2-18.—Bench-type drill press.

The controls of drill presses are all similar. The terms "right" and "left" are relative to the operator's position standing in front of and facing the drill press. Forward applies to movement toward the operator. Rearward applies to movement away from the operator.

The toggle switch (fig. 1-2-20) is located on the right side of the head assembly. The switch is single-pole single-throw. Start the

9180

11.9X

Figure 1-2-19.—Upright-type drill press.

motor by placing the switch in the "ON" position.

The spindle and quill feed handles (fig. 1-2-20) radiate from the spindle and quill pinion feed hub which is located on the lower right-front side of the head assembly. Pulling forward and down on any one of the three spindle and quill feed handles, which point upward at the time, moves the spindle and quill assembly downward. Release the feed handle and the spindle and quill assembly will return to the retracted or upper position by spring action.

The quill lock handle (fig. 1-2-21) is located at the lower left-front side of the head assembly. Turn the quill lock handle clockwise to lock the quill at a desired operating position. Release the quill by turning the quill lock handle counterclockwise. However, in most cases, the quill lock handle will be in the released position.

The head lock handle (fig. 1-2-21) is located at the left-rear side of the head assembly. Turn the head lock handle clockwise to lock the head assembly at a desired vertical height on the bench column. Turn the head lock handle counterclockwise to release the head assembly. When operating the drill press, the head lock handle must be tight at all times.

The head collar support lock handle (fig. 1-2-20) is located at the right side of the head collar support and below the head assembly. The handle locks the head collar support, which secures the head vertically on the bench column, and prevents the head from dropping when the head lock handle is released. Turn the head collar support lock handle clockwise to lock the support to the bench column and counterclockwise to release the support. When operating the drill press, the head collar support lock handle must be tight at all times.

The tilting table lock handle (fig. 1-2-20) is located at the left-rear side of the tilting table bracket. Turn the tilting table lock handle counterclockwise to release the tilting table bracket so it can be moved up and down or around the bench column. Lock the tilting table assembly at desired height by turning the lock handle clockwise. When operating the drill press, the tilting table lock handle must be tight at all times.

The tilting table lockpin (S, fig. 1-2-22) is located below the tilting table assembly (T, fig. 1-2-22). The lockpin secures the table at a horizontal or 45° left or right from the horizontal position. To tilt the table left or right from its horizontal position, remove the lockpin and turn the table to align the lockpin holes. Insert the lockpin through the table and bracket holes after desired position is obtained.

The depth gage rod adjusting and locknuts (BB and CC (fig. 1-2-22) are located on the depth gage rod (Z, 1-2-22). The purpose of the

Figure 1-2-22.—Drill press nomenclature.

adjusting and locknuts is to regulate depth drilling. Turn the adjusting and locknut clockwise to decrease the downward travel of the spindle. The locknut must be secured against the adjusting nut when operating the drill press.

When operating a drill press make sure the drill is properly secured in the chuck and that the work you are drilling is properly secured in position. Do not remove the work from the tilting table or mounting device until the drill press has stopped.

Operate the spindle and quill and feed handles with a slow, steady pressure. If too much pressure is applied, the V-belt may slip in the pulleys, the twist drill may break, or the starting switch in the motor may open and stop the drill press. If the motor should stop because of overheating, the contacts of the starting switch will remain open long enough for the motor to cool, then automatically close to resume normal operation. Always turn the toggle switch to "OFF" position while the motor is cooling.

44.61

Figure 1-2-23.—Electric powered grinder.

Check occasionally to make sure all locking handles are tight, and that the V-belt is not slipping.

Before operating any drill press, visually inspect the drill press to determine if all parts are in the proper place, secure, and in good operating condition. Check all assemblies, such as the motor, head, pulleys, and bench for loose mountings. Check adjustment of V-belt and adjust as necessary in accordance with the manufacturer's manual. Make sure the electric cord is securely connected and that the insulation is not damaged, chafed, or cracked.

While the drill press is operating, be alert for any sounds that may be signs of trouble, such as squeaks or unusual noise. Report any unusual or unsatisfactory performance to the petty officer in charge of the shop.

After operating a drill press, wipe off all dirt, oil, and metal particles. Inspect the V-belt to make sure no metal chips are imbedded in the driving surfaces.

BENCH GRINDER

The electric bench grinder (fig. 1-2-23) is designed for hand grinding operations, such as sharpening chisels or screw drivers, grinding drills, removing excess metal from work, and smoothing metal surfaces. It is usually fitted with both a medium grain and fine grain abrasive wheel; the medium wheel is satisfactory for rough grinding where a considerable quantity of metal has to be removed, or where a smooth finish is not important. For sharpening tools or grinding to close limits of size, the fine wheel should be used as it removes metal slower, gives the work a smooth finish and does not generate enough heat to anneal the cutting edges.

When a deep cut is to be taken on work or a considerable quantity of metal removed, it is often practical to grind with the medium wheel first and finish up with the fine wheel. Most bench grinders are so made that wire brushes, polishing wheels, or buffing wheels can be substituted for the removable grinding wheels.

To protect the operator during the grinding operation, an eye shield and wheel guard are provided for each grinding wheel. A tool rest is provided in front of each wheel to rest and guide the work during the grinding procedure. The rests are removable, if necessary, for grinding odd-shaped or large work.

When starting a grinder, turn it on and stand to one side until the machine comes up to full speed. There is always a possibility that a wheel may fly to pieces when coming up to full speed. Never force work against a cold wheel; apply work gradually to give the wheel an opportunity to warm. You thereby minimize the possibility of breakage.

Handle grinding wheels carefully. Before replacing a wheel always check it for cracks. Make sure that a fiber or rubber gasket is in place between each side of the wheel and its retaining washer. Tighten the spindle nut just enough to hold the wheel firmly; if the nut is tightened too much the clamping strain may damage the wheel. When selecting a replacement wheel, ascertain that the grinder will not exceed the manufacturer's recommended speed for the wheel.

When grinding, always keep the work moving across the face of the wheel; grinding against the same spot on the wheel will cause grooves to be worn into the face of the wheel. Keep all wheel guards tight and in place. Always keep the tool rest adjusted so that it just clears the wheel and is at or just below the center line of the wheel, to prevent accidental jamming of work between tool rest and wheel.

Wear goggles, even if eye shields are attached to the grinder. Keep your thumbs and fingers out of the wheel.

CUT-OFF SAW

The cut-off saw is a circular saw that is mounted on a radial arm. This arrangement is sometimes called a RADIAL ARM SAW. This machine is comparatively easy to move and is generally found on any woodworking job where there is quite a bit of sawing to do. The cut-off saw was primarily designed to cut boards off square but because of its versatility it can be used for ripping, cutting on an angle, dadoing, and many other wood cutting operations.

There are different types of cut-off saws available. The DeWalt (fig. 1-2-24) is commonly used in the Navy and is representative of what a cut-off saw is generally pictured to be. Its motor is incased in a yoke which is carriaged to travel to and fro in an overhead arm. The arm turns on a rigid column and can be adjusted up or down. Since the motor, too, can be turned and tilted, the whole relationship of components affords a flexibility of movement that will take care of nearly all woodworking operations.

Some of the latest models of cut-off saws have a built-in variable speed changer so you can select a suitable speed for the job being done. Some of them have an automatic brake so the saw blade stops in a few seconds when the switch is turned off.

Before you operate a radial arm saw, clean all dust and dirt from the blade, arbor face, and collar. The normal position of the blade is for the straight cut-off, where the blade is pulled from the rear to the front across the wood. The wood is placed on the table top with one side resting against the guide strip. For other operations where the cut is greater than that permitted in crosscutting, the wood is placed flat on the table against the guide and is moved by hand to the blade.

The arm may be pushed at any desired angle for angle cutting. For ripping and ploughing, the blade may be pulled out to the end of the arm and locked in position between the guide strip and the motor. In this operation, the wood is pushed along the guide strip from the side opposite the guard into the blade. For beveling, shaping, and routing, the motor may be tilted and locked at any angle.

The most important operating precautions for the cut-off saw are:

1. The electrical current being used should agree exactly with the specifications on the motor.
2. All clamp handles should be properly tightened before you operate the machine.
3. Before starting to cut, be sure that the wood rests against the guide strip in the cut-off position.
4. Before changing any setup, stop the saw.
5. For all operations, adjust the blade guard down to the material.

9185

44.62

Figure 1-2-24.—Cut-off saw (radial arm saw).

Periodical cleaning, greasing, and oiling of all moving parts are necessary. This should be done in accordance with the manufacturer's manual and is generally controlled by the petty officer in charge of the shop in which the saw is installed. Each morning before starting operations with the cut-off saw, you should clean the tracks inside the arm by wiping. Occasionally, clean these tracks with an approved cleaning fluid to remove grease and dirt.

PART I

Section 3

FASTENING DEVICES

Fastening devices are not tools; however, you will be using tools to install and remove them on any job that requires assembly or disassembly of equipment or structures.

Fastening devices, such as bolts, nuts, screws, and nails should be known by their names, sizes, and shapes. They are usually kept in storerooms or tool cribs and are issued when needed. When getting a fastener, you should know what you want so you can get the correct item in a minimum of time.

WOODWORKING FASTENERS

Before the development of nail-making, screw-making, and bolt-making machines, wooden members were held together by various types of interlocking joints that were reinforced with glue and wooden dowels. A dowel is a cylindrical hardwood pin which is driven into a hole bored to receive it, and which serves much the same purpose as a nail. Glued joints and joints fastened with wooden dowels are now confined mainly to furniture. Metal dowels are still used to fasten joints in window sashes, door members, and the like.

NAILS

Figure 1-3-1 shows the more common types of wire nails. The BRAD and the FINISH NAIL both have a DEEP COUNTERSINK head that is designed to be "set" below the surface of the work. The CASING nail has a FLAT COUNTERSINK head, which may be driven flush and left that way or which may also be "set." The other nails shown are all FLAT-HEADED nails. The COMMON nail is the one most widely used in general wood construction. Nails with LARGE FLAT heads are used for nailing roofing paper, plaster board, and similar thin or soft materials. DUPLEX or DOUBLE-HEADED NAILS are used for nailing temporary structures, such as scaffolds, which are eventually to be dismantled. A duplex nail has an upper and lower head. The nail is driven to the lower head; it can be easily drawn by setting the claw of a hammer under the upper head.

Besides nails with the usual type of shank (round) there are various more or less special-purpose nails with shanks of other types. Nails

Figure 1-3-1.—(A) Brad, (B) Finish nail, (C) Casing nail, (D) Box nail, (E) Common nail, (F) Spike (larger than 60d), (G) Duplex head nail.

9187

with SQUARE, TRIANGULAR, LONGITUDINALLY GROOVED, and SPIRALLY GROOVED shanks have a much greater holding power than wire nails of the same size. CONCRETE and MASONRY nails, designed to be driven into concrete or masonry, are hardened-steel nails which sometimes have longitudinally grooved shanks. A spirally grooved nail is called a SCREW nail.

The lengths of the most commonly used nails are designated by the PENNY system. This system originated in England, where the abbreviation for the word "penny" is the letter d (from DENARIUS, the Latin name of a Roman coin). Thus, the expression "a 2d nail" means "a twopenny nail." The thickness of a nail increases with the penny size and the number of nails per pound decreases. A box or casing nail of the same common nail penny size is thinner, and it takes more of them to weigh the same amount. The penny sizes and corresponding length, thicknesses (in gage sizes) and numbers per pound of the most commonly used nails are shown in figure 1-3-2.

Nails larger than 60d (which are called spikes), and nails smaller than 2d are designated by their lengths in inches or in fractions of an inch.

WOOD SCREWS

Wood screws are designated as to types by the type of head (fig. 1-3-3) and material, as "flathead brass," "roundhead steel or blue" and so on. Most wood screws are made of either steel or brass, but there are copper and bronze wood screws as well. To distinguish the ordinary type of head from the Phillips head, the former is called a SLOTTED head. A LAG screw is a heavy iron screw with a square bolt-type head; lag screws are used mainly for fastening heavy timbers.

The size of an ordinary wood screw is designated by the length and the BODY DIAMETER (unthreaded part) of the screw. Body diameters are designated by GAGE NUMBERS running from 0 (for about a 1/16-in. diameter) to 24 (for about a 3/8-in. diameter). Lengths range from 1/4 in. to 5 in. The length and gage number are printed on the box, as "1 1/4-9." This means a No. 9 gage screw 1 1/4-inches long. Note that for a nail, a large gage number means a small nail; but for a screw, a large gage number means a large screw.

BOLTS

A BOLT is distinguished from a wood screw by the fact that it does not thread into the wood, but goes through and is held by a NUT threaded onto the end of the bolt. Figure 1-3-4 shows the four common types of bolts used in woodworking. STOVE bolts are rather small, ranging in length from 3/8 in. to 4 in., and in body diameter from 1/8 in. to 3/8 in. CARRIAGE AND MACHINE bolts run from 3/4 in. to 20 in. long, and from 3/16 in. to 3/4 in. in diameter. The carriage bolt has a square section below the head, which is imbedded in the wood to prevent turning as the nut is drawn up. The machine bolt has a square head which is held with a wrench to prevent it from turning.

METAL FASTENING DEVICES

Many mechanisms and devices are held together with metal fasteners. Only the more commonly used fasteners will be discussed here so you will know when, where and how they should be used. If a flat point setscrew was used where specifications called for a cone point an important installation might fail at a crucial moment.

Metal parts can be fastened together with various fastening devices, such as rivets, bolts, screws, etc. Rivets and riveting are explained in another section. Bolts and screws are made in many shapes and sizes. Only the more common ones will be discussed in this course. ROUGH and SEMIFINISHED bolts and screws are pressed, hammered, or punched out of cold or hot metal. FINISHED bolts and screws are cut out of a bar of steel by machine.

Bolts and screws are used to fasten together parts that may have to be taken apart later. A bolt is used where you can get at both sides of the work with wrenches. A screw is used where only one side can be reached with a wrench or screwdriver.

STANDARDIZED

At one time each manufacturer made as many threads per inch on bolts, screws, and nuts as suited his own particular needs. For example, one made 12 threads per inch on 1/2" bolts while another might put on 13 or 15 threads per inch. Thus the bolts of one manufacturer would not fit the nuts made by another. The NATIONAL SCREW THREAD COMMISSION was

29.122

Figure 1-3-2.—Sizes of most commonly used nails.

established to study this problem and suggest a solution. This committee decided to standardize on a two-thread series, one called the NATIONAL COARSE THREAD SERIES (NC) and the other the NATIONAL FINE THREAD SERIES (NF). The SOCIETY OF AUTOMOTIVE ENGINEERS decided to standardize on some EXTRA FINE (EF) threads to be used in airplanes, automobiles, and other places where extra fine threads are needed. Figure 1-3-5 shows the number of threads per inch for NC, NF, and EF thread sizes up to 1 inch in diameter.

There have been four classes of fits established by the National Screw Thread Commission. They are: Class I, loose fit; Class II, free fit; Class III, medium fit; and Class IV, close fit.

The loose fit is for threaded parts that can be put together quickly and easily even when the threads are slightly bruised or dirty, and when

9183 6818 133

Figure 1-3-3.—Common types of wood screws.

Figure 1-3-4.—Common types of bolts.

a considerable amount of shake or looseness is not objectionable. The free fit is for threaded parts that are to be put together nearly or

Figure 1-3-5.—Screw threads per inch.

entirely with the fingers and a little shake or looseness is not objectionable. This includes most of the screw thread work. The medium fit is for the higher grade of threaded parts. It is the same as free fit, except that the fit is somewhat closer. The close fit is for the finest threaded work where very little shake or looseness is desirable and where a screwdriver or wrench may be necessary to put the parts together. The manufacture of threaded parts belonging to this class requires the use of fine tools and gages. This fit should, therefore, be used only where requirements are exacting or where special conditions require screws having a fine, snug fit.

MACHINE SCREWS

The term "machine screw" is the general term used to designate small screws used in tapped holes for the assembly of metal parts. Machine screws may be used with nuts, but usually they are screwed into holes that have been tapped with matching threads.

Most machine screws are made of steel or brass. They may be plated to help prevent corrosion. Special machine screws made of aluminum or stainless steel are obtainable; the

9190

latter are very strong and highly resistant to the corrosive action of salt water.

A great variety of diameters, lengths, and head shapes are manufactured. The complete description of machine screws must include the LENGTH in inches, THREAD-DIAMETER, HEAD SHAPE, MATERIAL from which made, and FINISH. Here is a typical example—"1/2 inch, 8-32, round head, brass, chromium plated, machine screw." The "8-32" means that the screw gage is No. 8 and that it has 32 threads per inch.

Machine screws are driven with a screwdriver or wrench, depending on the type of screw head.

Holes for FILLISTER-HEAD machine screws must be counterbored so that the heads will be flush with or below the surface.

Most of the time you will use the common types of machine screws shown in figure 1-3-6, but you may have occasion to use some of the special types shown in figure 1-3-7. Note that some of these special machine screws require special tools for driving and removing. These tools are usually included in a kit that comes with the machine or installation on which the screws are used.

Nuts are seldom used on machine screws, but square or hex nuts may be. When a nut is needed, make sure the threads of the bolt and nut are the same gage and pitch.

Figure 1-3-6.—Common types of machine screws.

Figure 1-3-7.—Special machine screws.

CAPSCREWS

Capscrews (fig. 1-3-8) are usually used without nuts, to hold parts of machines and engines together. They are screwed into tapped holes, and are sometimes referred to as tap bolts. Threads may be either NF or NC. Capscrews perform the same functions as machine screws, but come in larger sizes for heavier work. Sizes range up to 1 inch in diameter and 6 inches in length.

Figure 1-3-8.—Capscrews.

Capscrews may have square, hex, flat, button, or fillister heads. Fillister heads are best for use on moving parts because such heads are sunk into counterbored holes. Hex heads are usually used where the metal parts do not move.

The strongest capscrews are made of alloy steel, and can withstand great stresses, strains, and shearing forces. Capscrews made of stainless steel are often specified on machinery that is exposed to salt water.

Some capscrews have small holes through their heads. A wire, called a SAFETY WIRE, is run through the holes of several capscrews to keep them from coming loose.

STUDS

Studs might be called headless bolts. Both ends are threaded, one to screw into a tapped hole and the other to take a nut. (See fig. 1-3-9.)

Figure 1-3-9.—Studs.

9191

One important use of studs is to hold down the cylinder heads of boat and automobile engines. An important advantage of a stud over a bolt is that the nut can still be removed, even if the end screwed into the casting is "frozen". The end of the stud that screws into the casting usually has NC threads.

SETSCREWS

Setscrews are used to secure small pulleys, gears, and cams to shafts, and to provide positive adjustment of machine parts. They are classified by diameter, thread, head shape, and point shape. The point shape is important because it determines the holding qualities of the setscrew.

Setscrews hold best if they have either a CONE POINT or a DOG POINT, shown in figure 1-3-10. These points fit into matching recesses in the shaft against which they bear.

Figure 1-3-10.—Set screws and thumb screws.

HEADLESS SETSCREWS—slotted, Allen or Bristo types—are used with moving parts because they do not stick up above the surface. They are threaded all the way from point to head. COMMON SETSCREWS, used on fixed parts, have square heads. They have threads all the way from the point to the shoulder of the head.

THUMB SCREWS are used for setscrews, adjusting screws, and clamping screws. Because of their design they can be loosened or tightened without the use of tools.

NUTS

SQUARE and HEXAGONAL nuts are standard but they are supplemented by special nuts. (See fig. 1-3-11.) One of these is the JAM NUT, used above a standard hex nut to lock it in position. It

Figure 1-3-11.—Common kinds of nuts.

is about half as thick as the standard hex nut, and has a washer face.

CASTELLATED nuts are slotted so that a COTTER KEY may be pushed through the slots matching a hole in the bolt. This provides a positive method of preventing the nut from working loose. For example, you will see these nuts used with the bolts that hold the two halves of an engine connecting rod together. They are usually used with machine bolts.

WING NUTS are used where frequent adjustment is required. CAP, or ACORN nuts, are used where appearance is an important consideration. They are usually made of chromium plated brass. THUMB NUTS are knurled, so they can be turned by hand for easy assembly and disassembly.

ELASTIC STOP NUTS are used where it is imperative that the nut does not come loose. These nuts have a fiber or composition washer built into them which is compressed automatically against the screw threads to provide holding tension. They are used extensively on radio, sound equipment, fire control equipment and on aircraft.

WASHERS

Figure 1-3-12 shows the types of washers most used throughout the Navy. FLAT WASHERS are used to back up bolt heads and nuts, and to provide larger bearing surfaces. They also prevent damage to the surfaces of the metal parts through which a bolt passes.

SPLIT LOCK WASHERS are used under nuts to prevent loosening by vibration. The ends of these spring-hardened washers dig into both the nut and the work to prevent slippage.

SHAKEPROOF LOCK WASHERS have teeth or lugs that grip both the work and the nut. Several patented designs, shapes, and sizes are obtainable.

9132

here

Figure 1-3-12.—Washers.

KEYS AND PINS

COTTER KEYS (fig. 1-3-13) are used to secure castellated nuts on bolts and rods. They are also used as stops and holders on shafts and rods. SQUARE KEYS and WOODRUFF KEYS are used to prevent hand wheels, gears, cams and pulleys from turning on a shaft. These keys are strong enough to carry heavy loads if they are fitted and seated properly.

TAPER PINS are used to locate and position matching parts. They are also used to secure small pulleys and gears to shafts. They usually have a taper of 1/4-inch per foot. Holes for taper pins must be reamed with tapered reamers so they will fit properly.

DOWEL PINS are used to position and align the units or parts of an assembly. They are used in assemblies that must be frequently disassembled and assembled. One end of a dowel pin is chamfered, and it is usually .001 to .002 inch greater in diameter than the specified size. This allows the hole for the pin to be reamed to ensure a close fit.

Figure 1-3-13.—Keys and pins.

9193

PART II

Section 1

MEASURING

The ability to measure with any degree of accuracy depends upon the correct use of measuring tools. Section 1 of part I of this course describes the most common measuring tools you will use. In this section on "MEASURING" you will find some examples of measuring tools actually being used.

TAKING A MEASUREMENT WITH A COMMON RULE

To take a measurement with a common rule, hold the rule with its edge on the surface of the object being measured. This will eliminate errors which might result due to the thickness of the rule. Except in tapes, this thickness causes the graduations to be a slight distance away from the surface of the object. Read the measurement at the graduation which coincides with the distance to be measured, and state it as being so many inches and fractions of an inch. (See fig. 2-1-1.) Always reduce fractions to their lowest terms, for example, 6/8 inch would be called 3/4 inch.

44.66

Figure 2-1-1.—Measuring with and reading a common rule

MEASURING THE LENGTH OF A BOLT OR SCREW

The length of bolts and screws is best measured by holding them up against a rigid rule or tape. Hold both the bolt or screw to be measured and the rule up to your eye level so that your line of sight will not be in error in reading the measurement. As shown in figure 2-1-2, the bolts or screws with countersink type heads are measured from the top of the head to the opposite end, while those with other type heads are measured from the bottom of the head.

29.124A

Figure 2-1-2.—Measuring the length of a bolt or screw.

MEASURING THE OUTSIDE DIAMETER OF A PIPE

To measure the outside diameter of a pipe, it is best to use some kind of rigid rule. A folding wooden rule or a steel rule is satisfactory for this purpose. As shown in figure 2-1-3, line up the end of the rule with one side of the pipe, using your thumb as a stop. Then with the one end held in place with your thumb, swing the rule through an arc and take the maximum reading at the other side of the pipe. For most practical purposes, the measurement obtained by using this method is satisfactory. It is necessary that you know how to take this measurement as the outside diameter of pipe is the only dimension given on pipe specifications.

9194

Figure 2-1-3.—Measuring the outside diameter of a pipe.

MEASURING INSIDE DIAMETER OF PIPE WITH A RULE

To measure the inside diameter of a pipe with a rule, as shown in figure 2-1-4, hold the rule so that one corner of the rule just rests on the inside of one side of the pipe. Then, with one end thus held in place, swing the rule through an arc and read the diameter across the maximum inside distance. This method is satisfactory for an approximate inside measurement.

Figure 2-1-4.—Measuring the inside diameter of a pipe.

MEASURING THE CIRCUMFERENCE OF A PIPE

To measure the circumference of a pipe, a flexible type rule that will conform to the cylindrical shape of the pipe must be used. A web tape rule or a steel tape is adaptable for this job. When measuring pipe, make sure the tape has been wrapped squarely around the axis of the pipe (i.e., measurement should be taken in a plane perpendicular to the axis) to ensure that the reading will not be more than the actual circumference of the pipe. This is extremely important when measuring large diameter pipe.

Hold the rule or tape as shown in figure 2-1-5. Take the reading, using the 2-inch graduation, for example, as the reference point. In this case the correct reading is found by subtracting 2 inches from the actual reading. In this way the first 2 inches of the tape, serving as a handle, will enable you to hold the tape securely.

Figure 2-1-5.—Measuring the circumference of a pipe with a tape

MEASURING AN INSIDE DIMENSION USING A FOLDING RULE

To take an inside measurement, such as the inside of a box, a folding rule that incorporates a 6- or 7-inch sliding extension is one of the best measuring tools for this job. To take the inside measurement, first unfold the folding rule to the approximate dimension. Then extend the end of the rule and read the length that it extends, adding the length of the extension to the length on the main body of the rule. (See fig. 2-1-6.) In this illustration the length of the main body of the rule is 13 inches and the extension is pulled out 3 3/16 inches. In this case the total inside dimension being measured is 16 3/16 inches.

MEASURING AN INSIDE DIMENSION USING A TAPE RULE

In figure 2-1-7 notice in the circle that the hook at the end of the particular rule shown is

9195

Figure 2-1-6.—Using a folding rule to measure an inside dimension.

Figure 2-1-7.—Measuring an inside dimension with a tape rule.

attached so that it is free to move slightly. When an outside dimension is taken by hooking the end of the rule over an edge, the hook will locate the end of the rule even with the surface from which the measurement is being taken. By being free to move, the hook will retract away from the end of the rule when an inside dimension is taken. To measure an inside dimension using a tape rule, extend the rule between the surfaces as shown, take a reading at the point on the scale where the rule enters the case, and add 2 inches. The 2 inches are the width of the case. The total is the inside dimension being taken.

MEASURING AN OUTSIDE DIMENSION USING A TAPE RULE

To measure an outside dimension using a tape rule, hook the rule over the edge of the stock. Pull the tape out until it projects far enough from the case to permit measuring the required distance. The hook at the end of the rule is designed so that it will locate the end of the rule at the surface from which the measurement is being taken. (See fig. 2-1-8.) When taking a measurement of length, the tape is held parallel to the lengthwise edge. For measuring widths, the tape should be at right angles to the lengthwise edge. Read the dimension of the rule exactly at the edge of the piece being measured.

It may not always be possible to hook the end of the tape over the edge of stock being measured. In this case it may be necessary to butt the end of the tape against another surface or to hold the rule at a starting point from which a measurement is to be taken.

Figure 2-1-8.—Measuring an outside dimension using a tape rule.

HOW TO USE A STEEL TAPE OR WEB TAPE

Steel or web tapes are generally used for making long measurements. Secure the hook end of the tape to the outside edge, or corner, or end of the object to be measured. Hold the tape reel in the hand and allow it to unwind while walking in the direction in which the measurement is to be taken. Stretch the tape with sufficient tension to overcome sagging. At the same time make sure the tape is parallel to an edge or the surface being measured. Read the graduation on the tape by noting which line on the tape coincides with the measurement being taken.

MEASURING THE THICKNESS OF STOCK THROUGH A HOLE

To measure the thickness of stock through a hole with a hook rule, insert the rule through the hole, hold the hook against one face of the stock, and read the thickness at the other face. (See fig. 2-1-9.)

9196

44.7B

Figure 2-1-9.—Measuring the thickness of stock through a hole.

4.17B

Figure 2-1-10.—Using an outside caliper.

USING CALIPERS

A caliper is usually used in one of two ways. Either the caliper is set to the dimension of the work and the dimension transferred to a scale or the caliper is set on a scale and the work machined until it checks with the dimension set up on the caliper. To adjust a caliper to a scale dimension, one leg of the caliper should be held firmly against one end of the scale and the other leg adjusted to the desired dimension. To adjust a caliper to the work, open the legs wider than the work and then bring them down to the work. A sense of "feel" must be acquired to use calipers properly. This comes through practice and care in using the tool to eliminate the possibility of error. Always position the caliper properly on the axis of the work.

NOTE: Never set a caliper on work that is revolving in a machine.

The contact of one leg of a caliper on a revolving surface will tend to draw the other leg over the work because of the friction between the moving surfaces. Only a slight force is necessary to spring the legs of a caliper so that other measurements made with it are never accurate.

MEASURING THE DIAMETER OF ROUND STOCK OR THE THICKNESS OF FLAT STOCK USING AN OUTSIDE CALIPER

To measure the diameter of round stock, or the thickness of flat stock, adjust the outside caliper so that you feel a slight drag as you pass it over the stock. (See fig. 2-1-10.) After the proper "feel" has been attained, measure the setting of the caliper with a rule. Sight over the leg of the caliper after making sure the caliper is set squarely with the face of the rule.

MEASURING HARD TO REACH DIMENSIONS WITH A CALIPER

To caliper an almost inaccessible outside dimension such as the thickness of the bottom of a cup, use an outside transfer firm-joint caliper as shown in figure 2-1-11. When the proper "feel" is obtained, tighten the lock joint. Note that with the joint locked the auxiliary arm will remain in place. Loosen the binding nut and open the caliper enough to remove it from the cup. Close the caliper again and tighten the binding nut to seat in the slot at the end of the auxiliary arm. The caliper is now at the original setting, representing the thickness of the bottom of the cup. The caliper setting can now be measured with a rule.

To measure a hard to reach inside dimension, such as the internal groove shown in figure 2-1-12, a lock-joint inside caliper should be used. The procedure followed for measuring a hard to reach outside dimension is used.

MEASURING THE DISTANCE BETWEEN TWO SURFACES WITH AN INSIDE CALIPER

To measure the distance between two surfaces with an inside caliper, first set the caliper

Figure 2-1-11.—Measuring the thickness of the bottom of a cup

Figure 2-1-12.—Measuring a hard to reach inside dimension with an inside caliper.

to the approximate distance being measured. Hold the caliper with one leg in contact with one of the surfaces being measured. (See fig. 2-1-13.) Then as you increase the setting of the caliper, move the other leg from left to right. Feel for the slight drag indicating the proper setting of the caliper. Then measure the setting with a rule.

MEASURING THE DIAMETER OF A HOLE WITH AN INSIDE CALIPER

To measure the diameter of a hole with an inside caliper, hold the caliper with one leg in contact with one side of the hole (fig. 2-1-14) and, as you increase the setting, move the other leg from left to right and in and out of the hole. When you have found the point of largest diameter, measure the caliper setting with a rule.

MEASURING THE LENGTH OF A CURVE

To measure the length of a curve with dividers, step off the curve as you would step off a straight line. (See fig. 2-1-15.) First set the dividers to any small, even part of an inch. In setting a divider to a dimension on a scale,

Figure 2-1-13.—Measuring the distance between two surfaces with an inside caliper.

Figure 2-1-14.—Measuring an inside diameter with an inside caliper.

Figure 2-1-15.—Using a divider to measure the length of a curve.

9198

the usual procedure is to locate one point in one of the inch graduations of the rule and to adjust the divider so that the other point falls easily into the correct graduation. Make certain the points of the divider are not blunt. Extreme care is necessary in this setting because any error will be a cumulative error which increases as the length of the curve being measured increases. Then step off the curve, counting the number of "steps." This number, multiplied by the setting of the divider, will be only the approximate length of the curve, because you are stepping off a straight-line distance along a curved line, and a straight line is the shortest distance between two points. Therefore, the actual distance, or the length of the curve, will be a little greater than your totaled measurements. The accuracy of the totaled measurements will increase as the setting on the divider decreases.

MEASURING INSIDE AND OUTSIDE DIAMETERS WITH POCKET SLIDE CALIPERS

To measure the outside diameter of round stock, or the thickness of flat stock, with a pocket slide caliper, move the jaws of the caliper into firm contact with the surface of the stock. Read the measurement at the reference line stamped OUT. (See fig. 2-1-16.)

Figure 2-1-16.—Measuring an outside dimension with a pocket slide caliper.

To measure the inside diameter of a hole, or the distance between two surfaces, using a pocket slide caliper, insert only the rounded tips of the caliper jaws into the hole or between the two surfaces. (See fig. 2-1-17.) Read the measurement on the reference line stamped IN.

Figure 2-1-17.—Measuring an inside dimension with a slide caliper.

Note that two reference lines are needed if the caliper is to measure both outside and inside dimensions, and that they are separated by an amount equal to the outside dimension of the rounded tips when the caliper is closed.

MEASURING THE DEPTH OF A SLOT WITH A COMBINATION SQUARE

When using a combination square for measuring the depth of a slot, rest the squaring head on the surface of the work. (See fig. 2-1-18.) Loosen the blade friction screw and extend the blade to the bottom of the slot or shoulder, and retighten the screw to maintain the setting. Read the depth of the slot on the scale.

Figure 2-1-18.—Measuring the depth of a slot with a combination square.

9199 9200

MEASURING THE DEPTH OF A SLOT WITH A DEPTH GAGE

To measure the depth of a hole or slot with reasonable accuracy, use a depth gage as shown in figure 2-1-19 A. Hold the body of the depth gage against the surface from which the depth is to be measured and extend the scale into the hole or slot. Tighten the setscrew to maintain the setting. Withdraw the tool from the work and read the depth on the scale.

To measure the depth of a hole or slot with more accuracy than is possible with an ordinary depth gage, place a vernier depth gage over the slot as shown in figure 2-1-19 B. Notice the clamping screws are at X and Y; the horizontal adjusting screw nut is at Z. With X and Y loose, slide the scale down into the slot being measured until it is almost in contact. Then tighten X to make Z operative. With Z, adjust the scale to the "proper feel" and secure the setting with Y. By proper feel we mean the adjustment at which you first notice contact between the end of the scale and the bottom of the slot. Then read the setting as described under "Reading a vernier scale" in part I section 1 of this course.

To set the vernier depth gage to a particular setting, loosen both setscrews at X and at Y and slide the scale through the gage to the approximate setting. Tighten the setscrew at X, turn the knurled nut at Z until the desired setting is made, and tighten the setscrew at Y to hold the setting.

To measure the depth of a hole or slot, as shown in figure 2-1-19 C, with more accuracy than is possible with either an ordinary depth gage or a vernier depth gage, place a micrometer depth gage over the slot and adjust the thimble until the contact of the spindle causes the ratchet stop to slip. Remove the micrometer from the work and read the micrometer. Remember, if extension rods are used, the total depth reading will be the sum of the length of the rods plus the reading on the micrometer.

Figure 2-1-19.—Using depth gages.

MEASURING THE DIAMETER OF A HOLE WITH A SMALL HOLE GAGE

To measure the diameter of a hole from 1/8" to 1/2" in diameter, use a small-hole gage. (See fig. 2-1-20.) The four gages in a set cover this range of hole sizes so you must choose the proper gage for the size hole you are measuring. Insert the gage into the hole and adjust it to the hole size by turning the knurled tip of the handle. When you can feel the slight drag of the ball end on the sides of the hole, withdraw the gage. The size of the hole can then be determined by measuring the ball end of the gage with a micrometer caliper. Check part I, section 1 of this course if it is necessary to refresh your memory on how to read a micrometer.

Figure 2-1-20.—Measuring the diameter of a hole with a small hole gage.

MEASURING THE DIAMETER OF A HOLE WITH A TELESCOPING GAGE

To measure the diameter of a hole from 1/2" to 6" in diameter, select from a set of telescoping gages the one whose range includes the size you need. Loosen the knurled nut at the end of the handle, and telescope the adjustable end of the gage to a size slightly smaller than the hole and retighten the nut. Insert the gage into the hole as shown in figure 2-1-21, loosen the nut to permit the spring-loaded adjustable end to expand to the hole diameter, and tighten the nut. The spring loaded contact of the adjustable end will assure proper contact. Make sure, however, that the gage is held with the

9200 eere

Figure 2-1-21.—Using a telescoping gage.

telescoping end at right angles to the axis of the hole to measure the true, maximum diameter. Remove the gage and measure the setting with an outside micrometer caliper.

MEASURING THE DIAMETER OF A HOLE WITH AN INSIDE MICROMETER CALIPER

To measure the diameter of small holes from 0.2" to 1" in diameter, an inside micrometer caliper of the jaw type as shown in figure 2-1-22A may be used. Note that, in the inset the figures on both the thimble and the barrel are reversed, increasing in the opposite direction from those on an outside micrometer caliper, because this micrometer reads inside measurements. As you turn the thimble clockwise on this micrometer, the measuring surfaces move farther apart and the reading increases. On an outside micrometer caliper, as you turn the thimble clockwise, the measuring surfaces move closer together and the reading decreases.

For holes from 2" up to several feet in diameter, select the inside micrometer having measuring rods whose range includes the required dimension. The extension rod marked "6-7," for example, when inserted into the head of the micrometer, will measure inside diameters from 6" to 7". The soulder on the rod must seat properly to ensure a correct reading. Figure 2-1-22B shows that, for large measurements, both hands are used to set the micrometer for checking a diameter. Hold one end in place with one hand as you "feel" for the maximum possible setting by moving the other end from left to right, and in and out of the hole with the other hand. When no left-to-right movement is possible, and a slight drag is noticed on the in-and-out swing, take the reading.

Figure 2-1-22.—Measuring an inside diameter with an inside caliper.

MEASURING THE DISTANCE BETWEEN OUTSIDE SURFACES WITH A VERNIER CALIPER

To measure the distance between outside surfaces or the outside diameter of round stock with a vernier caliper, steady the stock with one hand and hold the caliper in the other as shown in figure 2-1-23. In the figure the clamping screws are at A and B; the horizontal adjusting screw nut is at C. With A and B loose, slide the movable jaw toward the piece being measured until it is almost in contact. Then tighten A to make C operative. With C, adjust the movable jaw to the proper feel and secure the setting with B. The reading can then be taken as explained in part I section 1 of this course.

MEASURING THE DISTANCE BETWEEN INSIDE SURFACES WITH A VERNIER CALIPER

To measure the distance between inside surfaces, or the inside diameter of a hole, with a vernier caliper, use the scale marked "inside." Figure 2-1-24 shows the measuring points in place. Remember that if you are using a vernier caliper with both metric and English scales, the scales appear on opposite sides of the caliper and apply only to outside measurements. Then, to get correct inside measurements, you add to the actual reading the measuring point allowance for the size of caliper you are using. Take this allowance from the table given in part I section 1 or the manufacturer's instructions. The actual measurement in this case is made in the same manner as taking an outside measurement.

9201

Figure 2-1-23.—Measuring an outside diameter with a vernier caliper.

Figure 2-1-25.—Measuring round stock with a micrometer caliper.

Figure 2-1-24.—Measuring an inside diameter with a vernier caliper.

MEASURING ROUND STOCK WITH A MICROMETER

When measuring the diameter of a small piece of round stock, hold the stock to be measured in one hand. Hold the micrometer in the other hand so that the thimble rests between the thumb and the forefinger. (See fig. 2-1-25.) The third finger is then in a position to hold the frame against the palm of the hand. The frame is supported in this manner and makes it easy to guide the work over the anvil. The thumb and forefinger are in position to turn the thimble either directly or through the ratchet and bring the spindle over against the surface being measured.

Turn the spindle down to contact by "feel," or else use the ratchet stop. Your feel should produce the same contact pressure and therefore the same reading as that produced when the ratchet stop is used. Develop your "feel" by measuring a certain dimension both with and without the aid of the ratchet stop. When you have the correct feel, you will get the same readings by both methods.

In measuring round stock the feel must be very light because there is only a line contact between the spindle and the stock and the anvil and the stock. Therefore the contact area is exceptionally small, causing a proportionally high contact pressure per unit of area. This would tend to give a reading smaller than the true reading unless the light feel is used. In measuring a ball from a ball bearing, the contact is at only two points, so the contact area is very small, indicating a tremendous pressure per unit of area. This condition requires only the lightest possible contact to give a true reading.

Hold the micrometer lightly and for only as long as is necessary to make the measurement. Wrapping the hand around it or holding it for too long a time will cause expansion of the metal and will introduce errors in measurement. Read the setting on the thimble scale (if the object is small) without removing the micrometer caliper from the object.

MEASURING A FLAT SURFACE WITH A MICROMETER CALIPER

When measuring a flat surface with a micrometer caliper, the entire area of both the

9202

anvil and the spindle is in contact with the surface being measured. This causes a proportionally low contact pressure per unit of area. Therefore the "feel" should be slightly heavier than when measuring round stock.

On large flat work, it is necessary to have the work stationary and positioned to permit access to the micrometer. The proper method of holding a micrometer when checking a part too large to be held in one hand is shown in figure 2-1-26. The frame is held by one hand to position it and to locate it square to the measured surface. The other hand operates the thimble either directly or through the ratchet. A large flat surface should be measured in several places to determine the amount of variation. It is good practice to lock the spindle in place with the locknut before removing the micrometer from the part being measured. After doing this the measurement indicated on the thimble scale can then be read.

To retain a particular setting, in cases where several pieces are to be gaged, lock the spindle in place with the locknut. When a piece is "gaged" with a micrometer with its spindle locked to a setting, the piece can quickly be identified as oversize, correct size, or undersize.

Figure 2-1-26.—Measuring flat stock with a micrometer caliper.

CORRECT MICROMETER ZERO SETTING

If an outside micrometer caliper does not read zero when the spindle touches the anvil, and both are clean at the point of contact, the zero setting should be corrected. This will eliminate the necessity of adding or subtracting a "zero correction" numerically to each reading as would otherwise be necessary if this adjustment were not made.

The zero setting on all micrometers is not made in exactly the same way. Refer to either the instructions that come with the micrometer or to the manufacturer's catalog for specific directions for a particular tool.

For example, The Brown & Sharpe Manufacturing Co. includes with each micrometer the instructions which follow, with an illustration of each step.

1. Carefully clean the measuring surfaces by pulling a piece of soft paper between the surfaces while the anvil and spindle are in light contact with the paper. Do not use hard paper. (See fig. 2-1-27A.)

2. With the anvil and spindle apart, unlock thimble cap with spanner wrench; then tighten cap lightly with fingers to bring light tension between thimble and spindle. (See fig. 2-1-27B.)

3. Bring anvil and spindle together by turning spindle and set zero line on thimble to coincide with line on sleeve. (See fig. 2-1-27C.)

4. Move spindle away from anvil by turning spindle and not by turning thimble. (See fig. 2-1-27D.)

5. Holding thimble only, tighten cap with fingers. Do not touch frame. (See fig. 2-1-27E.)

6. Lock cap with wrench, still holding thimble only, and the adjustment is complete. (See fig. 2-1-27F.)

It is IMPORTANT that you grip the micrometer as shown in each figure when making that particular adjustment. After completing the adjustment, check zero setting and make sure it is correct.

MEASURING THE PITCH OF A THREAD

The screw pitch gage has teeth which correspond to standard thread sections. To measure the pitch of a thread, compare it with the standards of the screw pitch gage by holding a gage

9203 4058

4.20.1D

Figure 2-1-27.—Correcting zero setting on a micrometer.

9204

Figure 2-1-28.—Using a screw pitch gage.

Figure 2-1-29.—Using a wire gage to measure sheet metal.

leaf to the thread being gaged until you find an exact fit. If possible, look at the fit toward a source of light, as a difference of one thread per inch, in the finer threads, is not easily detected.

As shown in figure 2-1-28, single and multiple threads can be gaged. The thread at A is single pitch, as the travel is one thread per revolution as shown by the dotted lines. The thread at B is a double pitch thread as shown by its dotted lines, and the travel is two threads per revolution. In this figure you see that the gage fits a certain thread, whether it be single or double pitch, internal or external thread.

MEASURING THE GAGE OF SHEET METAL

To measure the gage of a piece of sheet metal, first remove any burr from the place where you will apply the sheet metal gage.

The gage shown in figure 2-1-29 is used for gaging nonferrous sheet and wire. This gage, and others similar to it, are listed in the "Tables of useful information" under wire and sheet metal gages. Select, from the five gages listed in this table, the one that applies to the sheet of metal or wire you want to gage. For instance, column 2 of the above mentioned table tells you that the American Wire Gage shown in figure 2-1-29 is the one to use for nonferrous sheet and wire. Notice that usually each of the five gages has its own decimal equivalent for a particular gage number. If you have a piece of iron wire that is 0.016" in diameter, its correct identification is 0.016" diameter iron wire, B.W.G. (British Wire Gage) No. 27. If you have a piece of steel music wire that is 0.016" in diameter, you identify it as 0.016" diameter steel music wire, Music Wire Gage No. 6.

After the right gage has been selected, apply the gage to the wire, or to the edge of the sheet as shown in figure 2-1-29. The number opposite the slot that fits the wire or sheet is its gage number. The decimal equivalent is stamped on the opposite face of the gage.

To eliminate errors that might occur due to using the wrong gage, or if gages are not available, take a micrometer reading in decimal fractions of an inch and state the name of the material such as 0.014" hot rolled sheet steel, 0.010" brass wire, etc. Then to find the gage number, you can refer to the table on Wire and Sheet Metal Gages and find the material, the name of the proper gage, and the gage number corresponding to the decimal fraction obtained by taking a micrometer reading.

9205

THE IMPORTANCE OF ACCURATE MEASUREMENTS

In the performance of many jobs during your Navy career, accurate measurements of objects or material will be required.

More and more it is becoming common practice to fabricate parts and material for jobs in a shop for installation elsewhere on the ship or in the field. An example of this would be where you need a metal box a certain size to fit in a space in a compartment where you work. You would need to take the measurements of the space available and then send them to the sheet metal shop where the box would be built. This example shows clearly that both the measurements made by you and those made by the man making the box must be accurate.

9206

PART II

Section 2

LAYING OUT

Laying out work is the careful measuring and marking of stock prior to cutting and shaping the work. Close attention to details in layout is necessary to ensure successful progress on a job. The layout tools should be selected and used with care to ensure accurate layout work.

The plan for laying out a job may be taken from a blueprint or a sketch. The important thing to remember is to plan the layout to avoid delays in getting the job done and avoid waste of material.

Wood and metal are two common materials you will work with in the Navy. A marking awl or scriber is recommended for marking metal. An old saw file ground to a fine point makes a very good scriber if a commercial type scriber is not available. A center punch, or prick punch that is ground to a fine point, is valuable for marking locations for drill holes, bends, saw cuts, etc. To lay out lines on wood, pencils or a knife may be used for marking. To lay out rough work, a heavy carpenter's pencil may be used. To lay out lines for finish carpentry, a regular lead pencil sharpened to a conical point is used. For extremely accurate work, use a knife line for layout work.

The operations that are explained in this section are operations that you will perform when laying out lines on stock material prior to cutting and shaping the work.

SQUARING A LINE ON STOCK WITH A COMBINATION SQUARE

To square a line on stock with a combination square, place the squaring head on the edge of the stock, as shown in figure 2-2-1, and draw the line along either edge of the blade. The line will be square with the edge of the stock against which the squaring head is held; that is, the angle between the line and the edge will be 90 degrees.

Figure 2-2-1.—Squaring a line on stock with a combination square.

LAYING OUT A 45° ANGLE ON STOCK WITH A COMBINATION SQUARE

To lay out a 45° angle on stock, using a combination square, place the squaring head on the edge of the stock, as shown in figure 2-2-2, and draw the line along either edge of the blade. The line will be at 45° with the edge

Figure 2-2-2.—Using a combination square to lay out a 45° angle.

9207
8208

of the stock against which the squaring head is held.

DRAWING LINES PARALLEL TO AN EDGE WITH A COMBINATION SQUARE

To draw lines parallel to an edge, using a combination square, extend the blade from the squaring head a certain distance, such as the 2 inches shown in figure 2-2-3. Secure the blade at this position. Make a line parallel to the edge of the stock by holding the scratch awl or a pencil at the end of the blade as you move the square along the edge. All lines so made, with different blade settings, will be parallel to the edge of the stock, and parallel to each other.

Figure 2-2-3.—Drawing parallel lines with a combination square.

DRAWING ANGULAR LINES WITH THE PROTRACTOR HEAD OF A COMBINATION SQUARE

Remove the squaring head of the square and install the protractor head. Loosen the adjusting screw of the protractor head and rotate the blade to where the desired angle lines up with the index mark on the body of the head. The setting shown in figure 2-2-4 is 60 degrees. Retighten the screw to hold the setting. Hold the body of the protractor head in contact with a true edge of the work with the blade resting on the surface. Scribe or draw lines along the edge of the blade on the surface of the work. The angle set on the scale determines the angle

Figure 2-2-4.—Drawing angular lines with a combination square.

laid out on the work. All lines drawn with the same setting, and from the same true edge of the work, will be parallel lines.

FINDING THE CENTER OF ROUND STOCK

To locate the center of round stock, one of three tools is commonly used: the combination square, the hermaphrodite caliper, or a surface gage.

To use the combination square set for finding the center of round stock, remove the square head and protractor head by loosening their clamping nuts and withdrawing the rule. After removing these two heads, hold the center head firmly in place on the end of the shaft, as shown in figure 2-2-5, so that the shaft rests in the V of the center head and is in contact with the back of the rule. This will locate the one edge of the rule so that it passes through the center of the shaft. Scribe a line along this edge. Then relocate the center head at about 90° from this first line and scribe a second line. The intersection of these two lines will be the center of the end of the shaft.

Figure 2-2-6 shows the hermaphrodite caliper being used for locating the center of the end of a shaft. Hold the curved leg of the caliper against the shaft with one hand as you swing the arc holding the joint of the caliper with the other hand. The four points around

9208

28.21

Figure 2-2-5.—Locating a shaft center with a combination square.

the shaft where the curved leg is to be held are located approximately 90° apart. Any of the three patterns of scribed lines shown in figure 2-2-6 will serve as a guide to enable you to punch the center of the end of the shaft.

4.17L

Figure 2-2-6.—Locating the center of a shaft with hermaphrodite calipers.

The method for finding the center of a shaft by using a surface gage, vee-block, and a surface plate or similar true surface, is shown in figure 2-2-7. The vee-block holds the shaft at a fixed distance from the plate. The surface gage holds a scriber at a selected fixed distance from the plate. To locate the center on the end of the shaft, scribe a line that will be near the center. Rotate the shaft about 90° about its axis as it rests in the vee-block and scribe another line. When four lines have been scribed, they will serve as a guide to punching the center of the shaft. Do not move the setting of the scriber on the surface gage while making these layout lines.

When using a hermaphrodite caliper or a surface gage for finding the center of round stock, the methods shown will only give you an approximate center. The exact center can

28.25.1

Figure 2-2-7.—Locating the center of a shaft with a surface gage.

be found by drawing lines diagonally across the patterns scribed. Where the diagonal lines cross will be the exact center of the shaft.

When using any of the methods described for locating the center of a shaft, make sure the end of the shaft is reasonably square and clean. The use of layout dye or chalk, to emphasize the layout lines, will make them easier to see.

SOLVING BASIC PROBLEMS WITH THE FRAMING SQUARE

Of all the layout tools in the woodworker's kit, the framing square is far and away the most generally useful. The problems that can be solved when laying out work with the square are so many and varied that whole books have been written on the square along. Only a few of the most common uses of the square can be presented in this course.

The framing square is used most frequently to find the length of the hypotenuse (longest side) of a right triangle when the lengths of the other two sides are known. This is the basic problem involved, for example, in laying out or determining the length of a roof rafter, a brace, or any other member which forms the hypotenuse of an actual or an imaginary right triangle.

Figure 2-2-8 shows you how the framing square is used to determine the length of the hypotenuse of a right triangle with the other sides, each 12 in. long. Plane a true, straight edge on a board, and set the square on the board so as to bring the 12-in. mark on the tongue and the 12-in. mark on the blade even with the edge of the board. Draw the pencil marks shown

9209

Orse

in the second view. The distance between these marks, as measured along the edge of the board, is the length of the hypotenuse of a right triangle with the other sides each 12 in. long. You will find that the distance, which is called the BRIDGE DISTANCE, measures just a shade under 17 in. To be exact it is 16.97 in., as shown in the figure, but for most practical purposes the 16.97 may be rounded off to 17 in.

44.78

Figure 2-2-8.—Basic problem solved by the framing square.

In figure 2-2-8 the hypotenuse of the triangle is horizontal. In most practical situations, however, the triangle in question has one of the shorter sides horizontal and the other vertical. When this is the case, the length of the horizontal shorter side is called the RUN and the length of the vertical shorter side is called the RISE.

LAYING OUT 90° AND 45° ANGLES WITH A FRAMING SQUARE

In laying out 90° and 45° angles with a framing square, the lumber you work with will nearly always have to be squared on the ends. This will make it necessary to lay out a line at a 90° angle with respect to the edge of the board. This line should be as close to the end of the board as possible to avoid undue waste of material. When doing this job with a framing square, place the blade of the square along one edge of the board, and mark along the outside edge of the tongue, as shown in figure 2-2-9.

Ninety degree mitered corners are made by placing two 45° cuts together. To lay out a 45°

44.79

Figure 2-2-9.—Laying out a 90° angle with a framing square.

angle for making the cuts, place the framing square on the face of the board with an equal number of graduations on the tongue and blade as shown in figure 2-2-10, and mark along the edge of the square nearest the end of the board. If you want the angle with respect to the edge of the board to be opposite, merely turn the square over on its other side and again mark along the edge nearest the end. By making your layout lines nearest the edge of the board you will save material.

44.78A

Figure 2-2-10.—Laying out a 45° angle with a framing square.

LAYING OUT ROUNDED CORNERS ON SQUARE STOCK

To lay out a rounded corner on square stock, you will need a square and a set of dividers. Find the center of the arc (fig. 2-2-11) by measuring from the corner of the stock along the adjacent sides, a distance equal to the radius of the arc (A-A). Use a square and square in from points (B-B). The intersection of these lines will locate the center of the arc (C).

Set the dividers to a measurement equal to the distance of the radius of the arc (C-B).

9210 COSC

44.80

Figure 2-2-11.—Laying out a rounded corner on square stock.

Place one leg of the dividers at C, (fig. 2-2-11), and rotate the dividers around this point as a center, allowing the other leg to scratch lightly the surface of the stock. This arc should fall in line with the edges of the board at points (B-B).

FASTENING PAPER TO A DRAWING BOARD TO DRAW LINES

To fasten paper to a drawing board, place it on the board about an inch from the left-hand edge and near the top. (See fig. 2-2-12.) Placing the paper near the top of the board will keep the head of the T-square from running off the edge when you are working near the bottom of the paper.

Then true up the paper with the T-square blade, and secure it with thumbtacks or drafting tape at the upper corners only. The paper will then lie flat on the board.

To draw parallel horizontal lines, hold the head of the T-square to the edge of the board and draw lines as shown in figure 2-2-13.

To draw lines with a triangle and T-square, refer to figure 2-2-14 and note the directional arrows. Experience has shown that the best speed and accuracy are obtained by drawing your lines in these ways, provided of course, you are right handed; this applies to the 30°-60° triangle as well as the 45° shown in figure 2-2-14.

29.275B

Figure 2-2-12.—Squaring paper on a drawing board with a T-square.

29.275C

Figure 2-2-13.—Drawing horizontal lines with a T-square.

29.275A

Figure 2-2-14.—Drawing lines at an angle with a T-square and triangles.

9211

8158

DRAWING A LINE PARALLEL TO AN EDGE WITH A MARKING GAGE

To draw a line parallel to an edge with a marking gage, first determine the distance the line must be from the edge of the stock. Adjust the marking gage by setting the head the desired distance from the spur. Although the bar of a marking gage is graduated in inches, the spur may work loose or bend. If this occurs, accurate measurement should be made with a rule between the head and spur. (See fig. 2-2-15A.) To draw a line after setting the gage, grasp the head of the gage with the palm and fingers as shown in figure 2-2-15B; extend the thumb along the beam towards the spur. Press the head firmly against the edge of the work to be marked, and with a wrist motion tip the gage forward until the spur touches the work. Push the gage along the edge to mark the work, keeping the head firmly against the edge of the work.

Figure 2-2-15.—Using the marking gage.

DIVIDING A DIMENSION EQUALLY WITH A RULE

To divide a dimension, such as the 4" width of the board in fig. 2-2-16, into any given number of equal parts, place a rule on its edge across the face of the board. With the end of the rule at one edge of the board, adjust the rule at an angle to the other edge so that an inch graduation falls on the other edge. The 9" graduation would give nine equal divisions at the inch lines. The 6" graduation would give 6 equal divisions at the inch lines, or 3 by marking at the 2- and 4-inch lines, as shown. Then mark the divisions on the surface with a sharp pencil (fig. 2-2-16) and draw lines parallel with the working edge of the board.

Figure 2-2-16.—Dividing a dimension equally with a rule.

DIVIDING A LINE INTO EQUAL SEGMENTS WITH A DIVIDER

To divide a line equally with a divider, step it off in any size steps, as shown in figure 2-2-17, working from one end of the line to the other. When the end is reached, you will probably have a division which is smaller than the rest. This is a trial-and-error method; so either increase or decrease the setting on the divider until you obtain the required number of equal divisions.

Figure 2-2-17.—Dividing a line into equal segments with a divider.

9212

SCRIBING A LINE TO A SURFACE WITH A DIVIDER

Scribing a line to a surface is a skill used when doing such jobs as fitting linoleum into corners or curves, or fitting a piece of stock, as shown in figure 2-2-18, to a curved surface. In figure 2-2-18A, you see the complete fit. In 2-2-18B the divider has scribed a line from left to right. When scribing horizontal lines, the legs of the divider must be kept plumb (one above the other). When scribing vertical lines, the legs must be kept level. Therefore, to scribe a line to a surface, set the divider so that one leg will follow the irregular surface, and the other leg will scribe a line on the material that is being fitted to the irregular surface. (See fig. 2-2-18B.)

28.23

Figure 2-2-18.—Scribing a line to a surface.

When scribing a line on a level surface, as in fitting linoleum to a curved bulkhead, figure 2-2-19, keep the line joining the points of the divider perpendicular to the straight bulkhead from which you start to scribe.

LAYING OUT A PERPENDICULAR FROM A POINT TO A LINE

As shown in figure 2-2-20, to lay out a perpendicular from a point to a line using a divider, lightly prick punch the point, C, then swing any arc from C which will intersect the line AB, and prick punch the intersections D and E as shown in the figure. With D and E as centers, scribe two arcs, which intersect at a point such as F. Place a straightedge on points C and F. The line drawn along this straightedge from point C to line AB will be perpendicular (90°) to the line AB.

4.18C

Figure 2-2-19.—Scribing a line to fit linoleum to a curved surface.

28.26

Figure 2-2-20.—Laying out a line perpendicular to a line.

LAYING OUT A CIRCLE WITH A DIVIDER OR WITH TRAMMEL POINTS

To lay out a circle with a divider, set the divider at the desired radius, using a rule as shown in figure 2-2-21. Note that the 3-inch radius being set here is being taken away from the end of the rule. This reduces the chance of error, as each point of the dividers can be set on a graduation.

Place one leg of the divider at the center of the proposed circle, lean the tool in the direction it will be rotated, and rotate it by rolling the knurled handle between your thumb and index finger (fig. 2-2-22).

9213

4.18

Figure 2-2-21.—Setting a divider to a desired radius.

28.22.1

Figure 2-2-22.—Scribing a circle with a divider.

When setting trammel points, shown in figure 2-2-23, follow the same directions as for a divider, but use a steel tape or rule long enough to provide the larger radii that the trammel points can handle.

To lay out a circle with trammel points, hold one point at the center, lean the tool in the direction you propose to move the other point, and swing the arc or circle as shown in figure 2-2-23.

To transfer a distance measurement with trammel points, hold one point as you would for laying out a circle, and swing a small arc with the other point opened to the desired distance.

28.22.2

Figure 2-2-23.—Scribing a circle with trammel points.

PRICK PUNCHING THE INTERSECTION OF TWO LAYOUT LINES

To make the intersection of two layout lines, bring the point of the prick punch to the exact point of intersection and tap the punch lightly with a hammer. If inspection shows that the exact intersection and the punchmark do not coincide, as at A in figure 2-2-24, slant the punch as shown at B and again strike with the hammer, thus enlarging the punchmark and centering it exactly. When the intersection has been correctly punched, finish off with a light blow on the punch held in an upright position. C shows the corrected punchmark.

44.83

Figure 2-2-24.—Marking the intersection of lines with a prick punch.

9214

LAYOUT WITH DIVIDER AND PRICK FOR A LARGE HOLE

Where exactness is required in locating a hole for drilling, make a layout and drill a pilot hole to pilot or guide the final size drill. In general, as drill sizes increase and the thickness of the web at the point of the drill increases, a pilot hole becomes more of a necessity. The web of a drill, as shown at (A) in figure 2-2-25, is the solid center of the point extending the length of the flutes. As the web does not actually drill and remove chips, a pilot hole is necessary for accurate drilling, both to remove the metal in this area, and to provide a true path for the larger drill to follow. (See fig. 2-2-25B.) The accuracy with which the pilot hole is located and drilled determines, in part, the accuracy of the location of the final or "size" hole.

Figure 2-2-25.—Drilling a large hole.

To lay out a hole for accurate drilling, first apply layout dye sparingly to the surface to be laid out. Then place one leg of the divider in the prick punchmark which located the center of the hole and scribe a circle the size of the hole to be drilled. With the same center, scribe another smaller circle (called the pilot-hole proof circle), the diameter of which is equal to the diameter of the pilot drill. (See fig. 2-2-26A.) In figure 2-2-26, the size of the pilot hole has been greatly exaggerated compared to the pilot-hole size which would actually be used for the final-hole size shown. This is done only to clarify the illustration. Then, as shown in figure 2-2-26B prick punch both circles along their circumferences to complete the layout. In figure 2-2-26C, the pilot hole has been drilled to its layout line as indicated by the half prick punchmarks that remain on the pilot-hole proof circle.

PUNCH MATING PARTS WITH A CENTER PUNCH FOR REASSEMBLY

Before taking a mechanism apart, make a pair of center punchmarks in one or more places to help in reassembly. To do this, select places, staggered as shown in figure 2-2-27, where matching pieces are joined. First clean the places selected. Then scribe a line across the joint and center punch the line on both sides of the joint, with single and double marks as shown to eliminate possible errors. In reassembly, refer first to the sets of punchmarks to determine the approximate position of the parts. Then line up the scribed lines to determine the exact position.

Figure 2-2-26.—Laying out a hole for accurate drilling.

PART II

Section 3

TESTING, CHECKING AND SETTING

Many of the measuring and layout tools used by mechanics in the Navy also are used for inspecting a finished product or partly finished product. Inspection operations consist of testing, checking, and setting of a piece of work. This is accomplished by comparing the dimensions or shape of a piece of work with the required dimensions given on a drawing or sketch. There are many specialized tools especially made for checking certain jobs. It is not the purpose however, of this section to give detailed explanations of special tools, but rather to show how to use some of the more common handtools for testing, checking, and setting.

ADJUSTING A SLIDING T-BEVEL TO A DESIRED SETTING

To adjust a sliding T-bevel to a desired setting, loosen the blade screw, at the round end of the handle, just enough to permit the blade to slide along its slot and to rotate with slight friction.

To set the blade at a 45° angle, hold the handle against a framing square, as shown in figure 2-3-1A, with the blade intersecting equal graduations on the tongue and blade of the square. Or: hold the bevel against the edges of a 45° drafting triangle as shown in figure 2-3-1B. When using drafting triangles for setting a sliding T-bevel, different size triangles must be used for each different setting. A 45° angle can also be set by using the squaring head of a combination set as shown in figure 2-3-1C.

A sliding T-bevel can be set to any desired angle by using a protractor. Loosen the blade screw as before, and hold the bevel with its blade passing through the graduation selected, and the center of the protractor as shown at (D) in figure 2-3-1.

TESTING THE TRUENESS OF A CHAMFER OR BEVEL WITH A SLIDING T-BEVEL

To test a chamfer or bevel for trueness, set the T-bevel to the required angle, and hold the handle to the working face of the stock being tested. Face a source of light, and with the blade brought into contact with the surface to be tested, pass the blade along the length of the surface. (See fig. 2-3-2.) The appearance of light between the blade and the surface of the stock indicates where the angle is not correct. Figure 2-3-2 indicates the checking of a bevel, but testing the trueness of a chamfer is accomplished in the same way.

Figure 2-3-1.—Adjusting a sliding T-bevel to a desired setting.

TESTING TRUENESS OF A 45° ANGLE WITH A COMBINATION SQUARE

To test trueness of 45° angles with a combination square, hold the body of the square in contact with one surface of the 45° angle, and move the blade into contact with the other. (See

44.26B

Figure 2-3-2.—Testing the trueness of a bevel.

fig. 2-3-3.) In making this test, have the square between yourself and the source of light. If the angle is a true 45° angle, no light will be visible between the blade and the surface of the work.

TESTING TRUENESS OF A 90° ANGLE WITH A COMBINATION SQUARE

To test trueness of 90° angles with a combination square, hold the body of the square in contact with one surface of the 90° angle and bring the blade into contact with the other. (See fig. 2-3-4.) In making this test, have the square between yourself and a good source of light. If the angle is a true 90° angle, no light will be visible between the blade and the surface of the work.

SETTING A SURFACE GAGE FOR HEIGHT

To set a surface gage for height, first wipe off the top of a layout table or surface plate and the bottom of the surface gage. Use either a combination square or a rule with rule holder to get the measurement. A rule alone cannot be held securely without wobbling and consequently an error in setting generally results. Because a combination square is generally available, its use for setting a surface gage is explained in this section.

44.87

Figure 2-3-3.—Testing the trueness of a 45° angle with a combination square.

44.88

Figure 2-3-4.—Testing the trueness of a 90° angle.

Place the squaring head of a combination square on a flat surface as shown in figure 2-3-5, and secure the scale so that the end is in contact with the surface. Move the surface gage into position and set the scriber to the approximate height required, using the adjusting clamp that holds the scriber onto the spindle. Make the final adjustment for the exact height required (4 1/2 inches in this case) with the adjusting screw on the base of the gage.

LEVELING AND PLUMBING EQUIPMENT WITH A CARPENTER'S LEVEL

To level a piece of equipment, such as the workbench in figure 2-3-6, set a carpenter's level on the bench top parallel to the front

28.25

Figure 2-3-5.—Setting a surface gage to height.

9217

44.89

Figure 2-3-6.—Leveling a bench.

edge of the bench. Notice that the level may have as many as three or more pairs of glass vials. Regardless of the position of the level, always watch the bubble in the bottom vial of a horizontal pair. Shim or wedge up the end of the bench that will return that bubble to the center of its vial. Recheck the first position of the level before securing the shims or wedges.

To plumb a piece of equipment, such as the drill press shown in figure 2-3-7, place the level on the side and on the front of the main column of the press. Figure 2-3-7 shows the level on the side. Use shims as necessary to bring the bubble in the lower vial of either pair of the horizontal vials to the center in each case.

44.90

Figure 2-3-7.—Plumbing a piece of equipment with a level.

USING A PLUMB BOB

The plumb bob is used to determine true verticality. It is used in carpentry when erecting vertical uprights and corner posts of framework. Surveyors use it for transferring and lining up points.

To locate a point which is exactly below a particular point in space, when working ashore or on a ship in drydock, secure the plumb bob string to the upper point, such as A in figure 2-3-8. When the plumb stops swinging, the point as indicated at B in the illustration, will be exactly below A.

44.91

Figure 2-3-8.—Locating a point with a plumb bob.

To plumb a structural member, or an electrical conduit, as shown by figure 2-3-9, secure the plumb line A so that you can look at both the line and piece behind the line. Then, by sighting, line up the member or conduit with the plumb line.

9218

Figure 2-3-9.—Plumbing a structural member with a plumb bob.

If this cannot be done, it may be necessary to secure the plumb line at some point such as B, and then measure the offset from the line to the piece at two places so that, for example, C and D in figure 2-3-9 are equal. If the distances between C and D are not equal, adjust the structural member or conduit until they are.

USING A THICKNESS GAGE FOR CHECKING CLEARANCE BETWEEN SURFACES

To check clearance between surfaces, first clean the surfaces where the check will be made. Then insert blades of the thickness gage (fig. 1-1-86) into the clearance between the surfaces until a blade is found that enters with a slight drag. Then read the gage as follows.

In figure 2-3-10, the thickness gage leaf and the piston ring will both fit into the ring groove in the piston at the same time. Therefore, the number that appears on that leaf of the gage represents the number of thousandths of an inch of clearance there is between the piston ring and the side of the groove in the piston. All thickness gages have the thickness given on each leaf as a decimal part of an inch, such as 0.003", or 0.025". When necessary, two or more leaves can be used together for larger clearances. Keep the leaves clean and handle them with care so as not to cause damage to their edges or polished surfaces.

Figure 2-3-10.—Checking piston ring clearance with a thickness gage.

TESTING A SURFACE FOR FLATNESS

To test a surface for flatness, carefully clean it and remove all burrs. Then place the surface of the object on a flat area such as the surface plate in figure 2-3-11. Any rocking motion that is apparent will indicate a variance from flatness of the piece being tested.

Figure 2-3-11.—Testing a surface for flatness.

To determine how much variation there is from flatness—and where it is—you can insert leaves of a thickness gage to determine the amount of variation of flatness. Remember to add the thickness of all leaves together to get the total variation. (See fig. 2-3-12.)

For very fine work, lightly coat the surface plate with prussian blue (bearing blue) and move the piece being tested across the blue surface. (See fig. 2-3-13.) The low spots on the surface

Figure 2-3-12.—Checking the conformity of a flat surface.

9.19
0350

Figure 2-3-13.—Using prussian blue to aid in testing a flat surface.

being tested will not take the blue; the high spots will. See insert in figure 2-3-13.

A surface also may be tested for flatness with a straightedge. To do this, clean the surface thoroughly and hold the straightedge on the surface in several places as you look toward a source of light. The light showing between the surface being tested and the straightedge will reveal the low spots.

SETTING A COMBINATION FIRM JOINT CALIPER WITH A RULE

To set a combination firm joint caliper with a rule, when the legs are in position for outside measurements, grasp the caliper with both hands, as shown in figure 2-3-14A, and adjust both legs to the approximate setting. By adjusting both legs, the shape of the tool will be approximately symmetrical. Thus it will maintain its balance and be easier to handle.

Check this approximate setting and subsequent adjustments to the setting, as shown in 2-2-14B by resting one leg on the end of the rule. Sight squarely across the other leg at the graduations on the rule to get the exact setting required.

Figure 2-3-14.—Setting a combination firm joint caliper.

If it is necessary to decrease the setting, tap one leg of the caliper, as shown in figure 2-3-15A. If it is necessary to increase the setting, tap one leg of the caliper, as shown in figure 2-3-15B. In both illustrations the arrow indicates the change in setting that will take place.

Figure 2-3-15.—Decreasing and increasing the setting of a firm joint caliper.

When the caliper is set for inside measurements, the same directions for adjusting the setting apply. Figure 2-3-16 shows how the end of the rule and one leg of the caliper are rested on the bench top so that they are exactly even with each other when the reading is taken.

Figure 2-3-16.—Setting a combination firm joint caliper for inside measurements.

SETTING OUTSIDE AND INSIDE SPRING CALIPERS WITH A RULE

To set a particular reading on an outside spring caliper, first open the caliper to the approximate setting. Then, as shown in figure 2-3-17, place one leg over the end of the rule, steadying it with index finger. Make the final setting by sighting over the other leg of the caliper, squarely with the face of the rule at the reading, and turning the knurled adjusting nut until the desired setting is obtained. To

9220

4.17G

Figure 2-3-17.—Setting an outside spring caliper.

set an inside spring caliper to a particular reading, place both caliper and rule on a flat surface as shown in figure 2-3-18. The rule must be held squarely or normal (90° in both directions) to the surface to ensure accuracy. Adjust the knurled adjusting nut, reading the setting on the rule with line of sight normal to the face of the rule at the reading.

4.17H

Figure 2-3-18.—Setting an inside spring caliper.

TRANSFERRING MEASUREMENTS FROM ONE CALIPER TO ANOTHER

To transfer a measurement from one spring caliper to another, hold the calipers as shown in figure 2-3-19. Note that one of the man's fingers is extended to steady the point of contact of the two lower caliper legs. In this figure the inside caliper is being adjusted to the size of the outside caliper. As careful measurements with calipers depend on one's sense of touch, which is spoken of as "feel," calipers are best

4.17K

Figure 2-3-19.—Transfering a measurement from an outside to an inside caliper.

held lightly. When you notice a slight drag, the caliper is at the proper setting.

SETTING A DIVIDER TO REQUIRED DIMENSIONS

In setting a divider to a dimension on a scale, the usual procedure is to locate one point in one of the inch graduations of the rule and turn the knurled adjusting nut or screw so that the other point falls easily into the desired graduation. (See fig. 2-3-20.) Make certain the points of the divider are not blunt.

11.207A

Figure 2-3-20.—Setting a divider using a rule.

Most vernier calipers, except the larger sizes, have two center points similar to prick punchmarks. These are particularly useful in setting a divider to exact dimensions. One center point will be found near the zero end of the scale on the rule. The other point is in line with the first and to the left of the zero on the vernier scale. (See fig. 2-3-21.)

Set and secure the desired setting on the vernier caliper and adjust the divider until both points readily enter the center points on the vernier caliper as in figure 2-3-21.

TRANSFERRING A MEASUREMENT TO AN OUTSIDE MICROMETER

To transfer a measurement from an inside spring caliper, a telescoping gage, or an inside

9221 SSS

28.4K

Figure 2-3-21.—Setting a divider with a vernier caliper.

micrometer caliper to an outside micrometer caliper as shown in figure 2-3-22, proceed as you would to measure the outside diameter of round stock. In effect, you are simply measuring the setting of one of these tools with the outside micrometer. You proceed as you would in calipering round stock because the contact area is small and the contact pressure on the micrometer must be kept at a minimum. Use the ratchet stop, if the micrometer has one, to provide the correct pressure.

4.20.1E

Figure 2-3-22.—Transfering a measurement from an inside to an outside micrometer caliper.

The transfer of a measurement from the inside to the outside micrometer calipers can be a check on their accuracy, as both readings should be exactly the same. If they are not, first check the zero setting on each according to the manufacturer's instructions and make any necessary corrections. Then take a reading on a known dimension with the outside caliper such as on a gage block. This gage block must be somewhere between 1" and 2" in size, since the micrometer shown has a 1" to 2" range. If this reading does not check out, the threads on the spindle and in the sleeve of the outside micrometer are probably worn. This requires returning the micrometer to the manufacturer for repairs.

If the gage test shows the outside micrometer caliper to be correct, the trouble is likely with the threads on the inside micrometer caliper. It, also, must be sent to the manufacturer for repairs.

CHECKING HEIGHT WITH A DIAL INDICATOR

To check height with a dial indicator, support the indicator with a surface gage, as shown in figure 2-3-23. This figure shows the surface

44.98

Figure 2-3-23.—Checking the difference in heights of objects with a dial indicator.

gage and two objects resting on a surface plate. With the adjusting screw on the surface gage, move the indicator down into contact with the first object and secure the setting when the hand has moved about five-thousandths on the dial. Release the dial setscrew that is at the edge of the dial, rotate the dial to aline the zero with the hand, and retighten the setscrew. Then, without changing any of the adjustments, carefully slide the surface gage along the surface plate to take a dial indicator reading on the other object, or move the other object under the spindle of the dial indicator. The plus or minus reading on the dial will indicate the number of thousandths of an inch that the two objects differ in height.

9222 1556

If the second object being checked is more than five-thousandths of an inch shorter than the first, reset the dial indicator lower to get the difference reading.

TESTING THE TRUENESS OF SHAFTS AND WHEELS WITH A DIAL INDICATOR

To test the trueness of a shaft between centers (fig. 2-3-24), set up a dial indicator on a surface

44.99

Figure 2-3-24.—Testing the trueness of a shaft between centers.

gage so that the contact point of the spindle rests on the shaft near the middle. Now turn the shaft slowly as you watch the needle on the dial. A bent shaft, as it turns, will cause the spindle to move up or down. This motion is registered on the dial which is calibrated in one-thousandths of an inch. To read the total "runout" of the shaft, which means the amount it is bent out of line, loosen the dial setscrew that secures the rim of the indicator case and adjust the dial so that the zero coincides with the needle at one end of its travel. Then turn the shaft and take the reading at the other end of the needle's travel. This reading will indicate the number of thousandths of an inch the shaft is out of true, and it will enable you to find the high side as the shaft rotates.

To test the trueness of a wheel, gear, or sheave, set up the dial indicator so that its spindle is parallel to the shaft on which the wheel is mounted, and so that the tip of the spindle bears on the side of the wheel near its outer edge. As the wheel is rotated, the needle will indicate the runout in thousandths of an inch and enable you to find the place where it is at the maximum. (See fig. 2-3-25.)

44.100

Figure 2-3-25.—Testing the trueness of a wheel.

9223

PART II

Section 4

WOODCUTTING OPERATIONS

Although Navy ships are now made largely of steel and other metals, there are still plenty of woodcutting operations to be performed. Men in nearly all ratings should know how to make simple cuts and joints in wood.

More woodworking is done at Navy shore installations than aboard ship, but cruisers and larger ships have well-equipped carpenter shops. The smaller ships in the Navy have hand woodworking tools with which simple jobs can be performed.

Working with wood provides a good opportunity for advancement if you like a job that calls for initiative, imagination, patience, and skill. Regardless of your rating, you may be assigned duties on a Damage Control Team where it is necessary for you to do some woodworking. You may also be assigned as a helper to a Damage Controlman or a Builder; in which cases a basic knowledge of woodworking will be an asset.

SAWING A BOARD TO SIZE

One of the most important operations you will perform with wood is the proper laying out and cutting of stock lumber. Laying out is explained in part II, section 2, of this course.

It is important to determine at the beginning that the quality of stock fits your needs. Examine the stock for knots and checks, and lay out the job so that the imperfections will be cut away or will appear on the back side or underneath side where they will not be seen.

Check the stock to be certain that it is of proper size to ensure the required thickness and width of the piece you need. When laying out the job, keep in mind that there should be as little waste of material as possible.

USING A HAND SAW

To saw across the grain of the stock, use the crosscut saw, and to saw with the grain, use a ripsaw. Study the teeth in both kinds of saws so you can readily identify the saw that you need.

Place the board on a saw horse (fig. 2-4-1), or some other suitable object. Hold the saw in the right hand and extend the first finger along the handle as shown in the figure. Grasp the board as shown and take a position so that an imaginary line passing lengthwise of the right forearm will be at an angle of approximately 45 degrees with the face of the board. Be sure the

Figure 2-4-1.—Proper position for sawing a board to size.

side of the saw is plumb or at right angles with the face of the board. Place the heel of the saw on the mark. Keep the saw in line with the forearm and pull it toward you to start the cut.

To begin with, take short, light strokes, gradually increasing the strokes to the full length of the saw. Do not force or jerk the saw. Such procedure will only make sawing more difficult. The arm that does the sawing should swing clear of your body so that the handle of the saw operates at your side rather than in front of you.

Use one hand to operate the saw. You may be tempted to use both hands at times, but if your saw is sharp, one hand will serve you better. The weight of the saw is sufficient to make it cut. Should the saw stick or bind, it may be because the saw is dull and is poorly "set." The wood may have too much moisture in it, or you may have forced the saw and thus have caused it to leave the straight line.

Keep your eye on the line rather than on the saw while sawing. Watching the line enables you to see just the moment that the saw tends to leave the line. A slight twist of the handle, and taking short strokes while sawing, will bring the saw back. Blow away the sawdust frequently so you can see the layout line.

Final strokes of the cut should be taken slowly. Hold the waste piece in your other hand so the stock will not split when taking the last stroke.

Short boards may be placed on one sawhorse when sawing. Place long boards on two sawhorses, but do not saw so your weight falls between them or your saw will bind. Place long boards so that your weight is directly on one end of the board over one sawhorse while the other end of the board rests on the other sawhorse.

Short pieces of stock are more easily cut when they are held in a vise. When ripping short stock it is important that you keep the saw from sticking, so it may be necessary to take a squatting position. The saw can then take upward direction and thus work easily. When ripping long boards it will probably be necessary to use a wedge in the saw kerf to prevent binding (See fig. 2-4-2.)

44.102

Figure 2-4-2.—Using a wedge in a saw kerf to prevent binding.

USING PORTABLE CIRCULAR SAW

When you use a portable electric circular saw for cutting stock to size, make layout lines the same as if you were using a hand saw. Adjust the depth of the saw cut, never allowing more than 1/4 inch of the saw blade to protrude through the material. When crosscutting (across the grain) turn the ripping guide up out of the way. Start the saw by pressing the switch in the handle. Allow the saw to run for a few seconds to see that it is operating properly.

NOTE: You should never use a power saw unless you have been instructed in its use by a proficient operator.

Place the stock to be cut on sawhorses or other support in such a way that it will not change its position while being cut. Accidents might occur when the power saw is used to cut short pieces that might slip or that are hard to hold. Hold the board with one hand, and guide the saw along the layout line with the other.

Somewhere at the front of the shoe of the saw is a line which tells you the cut line of the saw blade. By keeping this line traveling on the pencil mark you will know the cut will be true. If you find that you are traveling off the line, do not attempt to force the blade back into line again. It is best to back out the blade and make a new approach.

At the start of the cut, be sure the blade is not making contact with the work. Rest the tool on the work, line up the cut guide with the layout line, and when the blade has attained full speed, start cutting. Wood does not have uniform density, therefore, the cut will be easier in some places than in others. This is especially true when you are cutting through a knot in the wood. If at any time the saw begins to labor, slow up the feed pressure. It is not advisable to release the switch when the blade stalls or approaches a stall; instead, back the blade out from the cut until the saw resumes full speed, and continue the cut. Ease up on the feed pressure to compensate for the additional density through which you are cutting.

9225

Never work with the tool resting on the portion of the work which is being cut off. If you do this, the tool will have no support at the end of the cut. Always position the tool on the main side of the cut. Position yourself where your body is out of the line of cut.

The cut itself should be made just outside of the layout line. Remember that the saw cut (kerf) has width, and that if you cut exactly on the line, you will be reducing the dimension you need by at least half the width of the kerf.

When ripping a board with a saw that is equipped with a rip guide, it is not necessary to make a layout line. Set the rip guide to the desired width of the board as shown in figure 2-4-3. Feed the saw into the material in the same manner as when crosscutting. Push the saw forward so that the ripping gage will slide along the edge of the board. Observe the same precautions in handling the saw as in crosscutting.

44.103

Figure 2-4-3.—Ripping with a portable circular, using a ripping guide.

USING A RADIAL ARM SAW (CUT OFF)

When using a radial arm saw for cutting stock to size, it is important that you follow the manufacturer's manual in making the adjustments of the saw and securing the locks. Review the information of radial arm saws in section I part 2 of this course if you have any doubt as to what adjustments must be made. While the relationship of parts is basically the same on all saws, adjustment procedures may vary, so study the literature that comes with the machine you are operating.

To cut a board to size, first do the crosscutting that is necessary. Make the layout lines the same as for any other job. Before placing the board on the table of the saw, start the saw and let it come up to operating speed, and pass the saw back and forth through the line of cut to make sure it operates properly.

Place the board to be cut on the saw table against the guide fence and make sure the layout line is in line with the line of cut of the saw. Place your left hand to the left of the saw blade travel. (See fig. 2-4-4.) Turn on the switch and pull the blade gradually through the work. Then return the blade to the starting position.

44.62A

Figure 2-4-4.—Crosscutting, using a radial arm saw.

The cut is complete when the blade has passed across the board width, but the operation is not complete until you have returned the blade to the rear of the arm travel. This is important: ALWAYS RETURN THE BLADE TO THE STARTING POSITION.

When ripping a board to size, push the work into the blade rather than pull the blade through the work. Set the saw blade parallel to the guide fence. Set the blade a distance from the guide fence equal to the width of the cut that you wish to make and lock the saw in position. (See fig. 2-4-5.)

Never feed the work in the direction of rotation of the blade. You must always feed against the rotation. Most saws are marked with arrows and warnings to help you remember correct feed direction for rip cuts.

9226

3352

Figure 2-4-5.—Ripping, using a radial arm saw.

One edge of the work rides against the fence so it is important that the blade (in rip position) and the fence be parallel. If binding occurs it is a good sign that the blade is not in parallel alignment with the fence.

Feed the work into the saw at a moderate speed, but not so fast that the saw will stall. Keep your hand that is doing the feeding well away from the cutting area. Use push sticks (fig. 2-4-6) to feed the work into the saw when you near the end of the cut. When the cut is complete, turn off the switch, then remove the work from between the blade and fence. Never do this while the blade is turning.

ASSEMBLING AND ADJUSTING A PLANE FOR CUTTING

Part I, section 1, of this course has given a complete description of the different types of planes that you are likely to use in the Navy. It may be necessary to refer to that section occasionally to refresh your memory as to the relationship and names of the parts that will be mentioned in this section.

To assemble the plane iron or blade and the plane iron cap for cutting, first hold the cap and blade as shown in figure 2-4-7A. Notice that the bevel on the blade is on the side opposite the cap side. When the head of the cap screw has dropped through the hole in the blade, slide it down the slot in the blade to the position shown

Figure 2-4-6.—Push stick for ripping.

in figure 2-4-7B. Then rotate the cap to the position shown in figure 2-4-7C, keeping the curved end of the cap well away from the cutting edge of the blade. Now slowly and carefully move the cap toward the cutting edge of the blade until it is about 1/32" away from the cutting edge as shown in figure 2-4-7D.

In part I section 1 figure 1-1-45A you will see the 1/32" setback from the end of the blade to the cap. The purpose of the cap is to curl the chips as they are cut off the wood by the cutting edge of the blade. This cap is sometimes called a chip breaker. The cap is fitted properly to the blade in figure 1-1-45A. Figure 1-1-45B shows a cap which has been improperly ground and therefore does not fit correctly. This will cause chips to become lodged between the blade and the cap. The improper fit may be corrected by filing or grinding the cap just behind its forward edge. In figure 1-1-45C the chip is being properly curled by the cap. Chips are curled so that they take a minimum of room, tend to break off as they increase in size, are

Figure 2-4-7.—Assembling a plane iron and cap for cutting.

less likely to foul the cap when coming out of the plane, and are more easily disposed of when swept from the bench top or the deck.

To complete assembly, and to adjust a plane for use, refer to figure 1-1-44. Place the assembled plane iron and cap in place, as shown in figure 1-1-44 (A and B), and be very careful to keep its delicate cutting edge from coming in contact with the other metal parts of the plane. The lug, shown in figure 1-1-44A, at the lower end of the lateral adjustment lever, must enter the slot in the blade. The upper end of the "Y" adjustment must enter the rectangular hole in the plane iron cap. The lever cap screw shown in figure 1-1-44C is used for adjusting the tension of the lever cap bearing on the plane iron cap. When the lever cap lever is down, as shown in 1-1-44C, and the lever cap is loose in its place, tighten the lever cap screw a quarter or a half turn at a time until the looseness disappears.

To adjust the plane for use (which means having the blade protruding through the bottom of the plane the proper amount, and having its edge parallel to the bottom of the plane), refer to figures 1-1-46 and 1-1-47. As you sight along the bottom of the plane, turn the adjusting nut until you can just barely see the blade protruding through the bottom of the plane. Figure 1-1-46 (B and C) shows you (greatly exaggerated) what to look for. The three views in figure 1-1-47 indicate how either one corner or the other of the plane iron can be withdrawn by moving the lateral adjusting lever from left to right. The final position of the lateral adjusting lever is not important. What is important is to have the blade protruding evenly across the width of the bottom of the plane.

PLANING STOCK TO GIVEN DIMENSIONS

To plane stock to given dimensions, a standard procedure is recommended. You will generally start with a piece of square stock. Part II, section 3, of this course shows you the best methods for testing stock for squareness.

Figure 2-4-8 shows the six standard steps to follow in planing any stock to given dimensions; to get accurate results, follow carefully the procedures shown.

To plane a chamfer, as shown in figure 2-4-9A, first make the layout on both sides of the corner to be chamfered. Figure 2-4-9 (B and C) show these layout lines being made with a marking gage.

To plane the chamfer on an edge secure the stock in a vise, if possible, as shown in figure 2-4-10A. As you are planing to two layout lines, watch both lines carefully so that both lines are reached at the same time. Figure 2-4-10B shows an end view of planing a chamfer on an edge.

To plane a chamfer on the end of a piece of stock, secure the stock and plane as shown in figure 2-4-11. Notice carefully the angle at which the plane is being held. Move the plane according to the directional arrow shown in the figure, and work from left to right until the entire width of the stock has been chamfered. Layout lines are used as before.

To plane a bevel only one layout line is required due to the fact that the opposite edge of the stock serves as the other layout line. Plane the bevel as you would plane a chamfer, holding the stock in a vise.

To plane across end grain, figure 2-4-12A, hold the block plane at an angle so that the blade will make a shearing cut. Block-plane adjustments are basically the same as those for smoothing and jack planes. See figure 2-4-12B. To assemble a block plane, which has a cap similar to the lever cap on a smoothing plane but has no plane iron cap, insert the blade carefully into the body with the bevel up. This position of the plane iron is just opposite to the plane iron position in planes with lever caps. A block plane has a very low blade angle to facilitate planing across grain. If the plane-iron bevel were down, its heel would not permit the cutting edge to come into contact with the surface of the work.

To see how to prevent splitting the edge of the stock when planing across its end, refer to figure 2-4-13. At (A) the presence of the layout line indicates that the board has not yet been planed to its required width. The splitting that occurs is therefore in the scrap area. At (B) the end is first planed from one edge toward the middle and then from the other. No splitting ever takes place when the plane enters the cut, but does occur when it leaves the cut at the edge of the work. In this method it does not leave the cut at the edge. At (C) a bar clamp holds a piece of scrap stock in place to back up the job at one edge. Again splitting occurs, but in the scrap stock.

44.108

Figure 2-4-8.—Steps to follow in planing any stock to a given size.

USING A DRAWKNIFE (DRAWSHAVE) FOR ROUGHING OUT A CURVE

A drawknife is useful for roughing out a curve or any irregular surface in lumber. This is especially true where a large amount of waste material must be removed.

To use a drawknife, first make the layout lines on the stock material where they are needed. Clamp the stock in a vise or otherwise hold it securely. The drawknife is always pulled toward the operator with both hands and since, in most cases, you will be cutting both with and across the grain of the stock, it is advisable to work first on one side of the cut then the other. This procedure will lessen the chances of splitting the stock. Keep the bevel side of the blade up for ordinary work, and move one end of the blade slightly ahead of the other to give an oblique or sliding cut. This gives better control of the tool and enables you to cut to the layout line more easily.

After you have removed most of the excess material from the cut, use a wood rasp or sandpaper to smooth the cut even with the layout lines.

BORING HOLES IN WOOD

Boring holes is frequently necessary when working with wood. It is important, therefore, that you know the proper procedures and the tools that are used for this job.

9229

44.109

Figure 2-4-9.—Laying out for planing a chamfer.

Figure 2-4-13.—Preventing spliting when planing the edge of stock.

29.12G

Figure 2-4-11.—Planing a chamfer on the end of a piece of stock.

44.111

Figure 2-4-14.—An auger bit file.

The auger bit is the tool that actually does the cutting in the wood; however, it is necessary that another tool be used to hold the auger bit and give you enough leverage to turn the bit. The tools most often used for holding the bit are the carpenter's brace, breast drill, push drill, and the drill press. All of these tools have been introduced in part I of this course.

For accurate boring, first mark the location for the center of the hole by the intersection of two cross lines, or by a small hole made with an awl or other sharp-pointed tool. As the auger starts boring, be careful to keep it perpendicular to the surface (unless you are boring the hole at an angle). To see that the auger is boring square with the surface, step back a little, steadying the brace or drill with one hand, and sight; then move around and sight in another direction about at right angles to the first direction of sighting. A square may also be used to see if the bit is going straight. It is

9230

In sharpening this screw, follow the original twist and thread pattern, removing the small nicks and sharpening the crest or top of the spiral thread. Rather than risk damaging the feed screw when large nicks are present, just touch up the rough edges of the nick so they will not tear the fibers of the wood when a hole is bored. A large nick treated in this way will put back into service a bit which otherwise might have to be surveyed. See figure 2-4-18.

Figure 2-4-18.—Sharpening an auger bit feed screw.

SHARPENING AN EXPANSIVE BIT

To sharpen an expansive bit, sharpen the feed screw just as you would for an auger bit. This will be necessary only if the screw has been damaged by striking nails or being dropped on a hard surface. The three edges of the bit which normally require sharpening are identified in figure 2-4-19 as blade spur, blade-cutting edge, and body-cutting edge. An expansive bit may also have a body spur which would be sharpened as an auger bit spur is sharpened.

To sharpen the cutting edge of the blade, remove the blade from the body and hold it in the vise as shown in figure 2-4-20A. The removable soft jaws will protect the blade from damage. Using an auger bit file, file toward the cutting edge. Maintain angle A by filing the entire surface behind the cutting edge. Note that in figure 2-4-20A the file is in contact with the entire surface.

As filing progresses, a burr will form along the blade-cutting edge on the hollow face of the

Figure 2-4-19.—Points to be sharpened on an expansive bit.

blade. Remove this with a round edge slip stone, holding the blade in one hand and the stone in the other. See figure 2-4-20.

To sharpen the spur, while the blade is in the vise, proceed as you would to sharpen the spur on an auger bit. This is illustrated in figure 2-4-16.

To sharpen the body-cutting edge, first note its cutting-edge angle and its clearance angle shown in figure 2-4-21A.

Maintain this original shape to provide strength behind the cutting edge. File toward the cutting edge, steadying the bit on the edge of the bench as shown in figure 2-4-21B.

A burr will form on the side opposite the one you have filed. To remove this burr, hold the bit as shown in figure 2-4-21C and file toward the cutting edge, holding the file flat on the surface of the metal behind the cutting edge.

BORING THROUGH HOLES IN WOOD

To bore a through hole in wood with an auger bit, first select the proper fit. Note the figure stamped on or near the square tang. This figure indicates the size, in 16ths of an inch, of the hole that the bit will bore. See figure 2-4-22.

To chuck the bit, hold the shell of the chuck (fig. 2-4-23A) as you turn the handle to open the jaws. When the jaws are apart far enough to take the square tang of the bit, insert it

Figure 2-4-20.—Sharpening the cutting blade of an expansive bit.

(fig. 2-4-23B) until the end seats in the square driving socket at the bottom of the chuck. Then tighten the chuck by turning the handle to close the jaws and hold the bit in place.

With a chuck having no driving socket (a square hole which is visible if you look directly into the chuck), additional care must be taken to seat and center the corners of the tapered shank in the V grooves of the chuck jaws. See figure 2-4-23C. In this type of chuck the jaws serve to hold the bit in the center and to prevent it from coming out of the chuck.

After placing the point of the feed screw at the location of the center of the hole you will bore, steady the brace against your body, if possible, with the auger bit square with the surface of the work.

To bore a horizontal hole in stock held in the bench vise, hold the head of the brace with one hand, steadying it against your body, while turning the handle with the other hand. Scrap stock behind the job will prevent splintering. See figure 2-4-24.

When it is not possible to make a full turn with the handle of the bit brace, turn the cam ring, shown in figure 2-4-23A, clockwise until it stops. This will raise one of the two ratchet pawls affording clockwise ratchet action for rotating the bit. For counterclockwise ratchet action, turn the cam ring counterclockwise as far as it will go.

To bore a vertical hole in stock held in a bench vise, hold the brace and bit perpendicular to the surface of the work. Placing a trysquare near the bit, alternately in the two positions shown in figure 2-4-25, will help you sight it in.

Another way to bore a through hole without splitting out on the opposite face is to reverse the bit one or two turns when the feed screw just becomes visible through this opposite face (fig. 2-4-26A). This will release the bit. Remove the bit while pulling it up and turning it clockwise. This will remove the loose chips from the hole. Finish the hole by boring from the opposite face. This will remove the remaining material which is usually in the form of a wooden disk held fast to the feed screw. See figure 2-4-26B.

To bore through holes with an expansive bit, you must first clamp a piece of scrap stock behind the job as shown in figure 2-4-27. Then bore through the job and into the scrap stock a few turns, thus leaving a clean cut on the job itself. This method is, of course, also satisfactory when using auger bits. However, boring from both faces, as shown in figure 2-4-26 with an auger bit, does not work well with an expansive bit.

BORING HOLES IN WOOD TO A REQUIRED DEPTH

To bore a hole to a certain depth, especially when several holes of the same depth are needed, use a bit gage. This tool, shown in figure 2-4-28, will fit auger bits up to 1 inch and is clamped onto the bit as shown. When the two flats on the bottom of the gage come into contact with the surface of the board into which the hole is being bored, the feed screw cannot function. The hole will remain at that particular depth even though the bit is kept turning. The depth setting will be the distance the gage flats are set from the cutting edges of the bit.

9233

Figure 2-4-21.—Sharpening the body cutting edge of an expansive bit.

Figure 2-4-22.—Size markings on auger bits.

A block of wood, with a hole bored lengthwise through it, can be used as a depth gage. Cut the block to whatever length will provide the desired depth setting. See figure 2-4-29 on how to use it.

To bore a hole to a given depth without any type of gage, turn the bit until the cutting edges just start to cut. Then measure the distance, with your rule, from the surface of the wood to the bottom face of the chuck. As you bore the hole, this measurement will decrease. The amount of decrease is the depth of the hole. As an example, if the initial measurement was 5 inches, and after boring for several turns of the auger bit the measurement is 4 inches, the hole will be 1 inch deep. (See figure 2-4-30 (A and B).)

When accuracy is not important, you can measure from the cutting edges of the bit a distance equal to the required depth of the hole and put a mark on the twist of the bit. Bore the hole until this mark, which might be a

9234

Figure 2-4-23.—Placing an auger bit in a chuck.

Figure 2-4-24.—Using scrap lumber to prevent splintering when boring.

crayon or pencil mark, reaches the surface of the wood. A piece of friction or scotch tape will serve as a marker, too. (See figure 2-4-30C.) These latter two methods of boring a hole to a certain depth are used when only one hole is to be bored to that depth.

To bore a deep hole, chuck an auger bit in an auger-bit extension and chuck the auger-bit extension in the bit brace.

The effective length of the auger bit will be increased by about the length of the extension,

Figure 2-4-25.—Method of sighting in for perpendicular hole.

Figure 2-4-26.—Boring a through hole by reversing direction.

Figure 2-4-27.—Drilling a through hole with an expansion bit.

Figure 2-4-28.—Boring a hole using a bit gage.

Figure 2-4-29.—Using a block of wood as a depth gage.

Figure 2-4-30.—Boring a hole to a given depth without a gage.

thus enabling you to bore overhead holes, holes which are located so that the bit and brace alone could not reach them, and deep holes. Note that the minimum-size hole that the extension itself will follow into is the diameter of the chuck plus some clearance. (See figure 2-4-31.) This limits its use in boring deep holes to that size or larger, but does not limit its use in boring in hard-to-reach places. If the extension is not to follow into the hole, it may be used with smaller bits. The auger-bit extension is not designed to handle sizes larger than 1" which take more turning force than it will stand. (See figure 2-4-31.)

Figure 2-4-31.—Using an auger bit extension.

DRILLING HOLES WITH A TWIST DRILL

An ordinary twist drill may be used to drill holes in wood. Select a twist drill of the size required and secure it in the chuck of a power- or hand-operated drill.

In figure 2-4-32 the twist drill has been chucked in the chuck of a drill press. Notice that the job is secured to the table of the drill press with a pair of C-clamps. Beneath the job is a block of wood. In drilling through wood, a backup block is used to ensure a clean hole at the bottom of the job.

Figure 2-4-32.—Drilling a hole in wood with a twist drill.

An electric hand drill secured in a drill stand will serve in a limited way to take the place of a drill press. However, only the one speed is available and must be used for small and large twist drills alike. When the electric drill is used in a drill stand, rather than offhand, less effort is necessary to feed the drill into the metal. Also, because the drill is rigidly mounted, less drill breakage is to be expected. In addition, holes will be drilled at right angles to the surface of the work in either

the drill stand or the drill press more easily than if the electric drill is held by hand.

Figure 2-4-33 shows a hole being drilled with a breast drill. Turn the crank handle with one hand as you hold the side handle with the other hand. This will steady the breast drill while feed pressure is applied by resting your chest on the breast plate shown in figure 2-4-33. Notice, in figure 2-4-33, that the breast drill has a high or a low speed available, according to the setting of the speed selector nut. When drilling a horizontal hole, apply feed pressure by resting your body against the breast plate.

4.33A

Figure 2-4-33.—Drilling a hole with a breast drill.

In drilling a horizontal hole with the hand drill shown in figure 2-4-34, operate the crank with the right hand and with the left hand guide the drill by holding the handle which is opposite the chuck end of the drill. Get additional feed pressure, if necessary, by carefully leaning against the hand drill with your body.

4.34A

Figure 2-4-34.—Drilling a hole with a hand drill.

DRILLING HOLES WITH A "PUSH" DRILL

Figure 2-4-35A shows the Stanley "Yankee" automatic drill which is often called a "push" drill. This drill can be used to drill either horizontal or vertical holes when the accuracy of the right angle with the work is not critical.

The drill point used in push drills (fig. 2-4-35B) is a straight flute drill. Sharpen its point on the grinder and provide only slight clearance behind the cutting edge. It will drill holes in wood and other soft materials.

To select a drill for use in a push drill, hold the handle of the drill in one hand and release the magazine by turning the knurled screw as shown in figure 2-4-36A. This will permit you to drop the magazine. Figure 2-4-36B shows the drill magazine lowered to expose the drills from which the proper size can be selected.

44.116

Figure 2-4-35.—Push drill and drill point.

9237

Figure 2-4-36.—Selecting a drill for use in a push drill.

To chuck the drill, loosen the chuck several turns and insert the drill as far as it will go. Turn the drill until it seats in the driving socket in the bottom of the chuck. Then tighten the chuck to hold the drill in place. See figure 2-4-36C.

To drill a vertical hole with this drill (fig. 2-4-37A), place the job on a flat surface and operate the push drill with alternate strokes up and down. If it is necessary to hold the work in place while it is being drilled, use some mechanical means if you can. If you must hold the job with your hand, grasp the material as far as possible from where the drill is drilling.

In drilling horizontal holes with the push drill, as in figure 2-4-37B, secure the job in a vise. The back-and-forth strokes rotate the drill, advancing it into the work on the forward stroke as the drilling proceeds. The index finger, extended along the body of the tool, will help guide the drilling at right angles to the work.

Figure 2-4-37.—Drilling horizontal and vertical holes with a push drill.

DRILLING HOLES FOR WOOD SCREWS

To drill a hole for a wood screw which is used to hold two pieces of hard wood together, as shown in figure 2-4-38, two different sized holes are usually necessary. The wood screw simply passes through the hole in the top piece and the threads take hold in the bottom piece.

Figure 2-4-38.—Using a screw to hold two pieces of wood together.

In this case, drill the body hole, as shown in figure 2-4-39, completely through the top piece. Notice in figure 2-4-39 that the point of the body drill has just entered the bottom piece.

Figure 2-4-39.—Shape of hole for a wood screw.

Then drill the "starter" hole which is the root diameter (or a little less) of the wood screw and therefore somewhat smaller than the body hole. Insert the starter drill through the body hole and continue the drilling with the body hole as a guide. If a flathead wood screw or oval-head wood screw is to be used, countersink the body hole as shown. (Refer to fig. 2-4-43 on how to countersink holes in wood.)

Select the drill sizes according to the dimensions of the wood screw. The names of these dimensions are given in figure 2-4-40.

9238

Figure 2-4-40.—Nomenclature of a wood screw.

Figure 2-4-41.—Types of wood screws.

Figure 2-4-41 shows the three most common types of wood screws. Notice that the length is always measured from the point to the greatest diameter of the head. As a general rule, the length of the wood screw should be such that the body shown in figure 2-4-40 extends through the piece being screwed down so that the threaded portion will then enter the piece of wood beneath it.

Determine the size of the body hole by holding the body of the screw in front of the graduations on a rule and taking a reading. Then determine the size of the root diameter hole by using the same method and measuring at about the middle of the threaded portion of the screw. Neither of these measurements is critical. Another way to find out what size drills to use for the body hole and the starter hole, when you know the size number of the wood screw you are using, is to refer to the chart shown in figure 2-4-42. To do this, find the proper column according to the size number of the screw, such as No. 14 for instance. Reading down the column you will find that the decimal diameter of its shank is 0.242", or 15/64" stated in a common fraction. You will also find the the body hole should be drilled with a 1/4" twist drill or bored with a No. 4 auger bit, and that the starter hole should be drilled with a 5/32" twist drill. Where no figure is given in the chart for bit size, use the recommended twist drill size. A No. 4 auger bit is the smallest size (1/4") generally available. Because a No. 1 screw is so small, no starter hole is required and therefore no drill or bit sizes are given.

COUNTERSINKING HOLES IN WOOD

To countersink a hole in wood, use a countersink, three types of which are shown in figure 2-4-43. Any one of these will do the job. Turn the countersink at slow speed to ensure a smooth surface on the countersunk portion of the hole.

Countersink deeply enough so that the major diameter of the screwhead is at or just slightly below the surface of the work. Figure 2-4-44 shows one way of determining the proper depth of the countersunk portion of the hole. If many holes are to be countersunk on the drill press, set the depth stop when the proper setting has been determined.

USING WOOD CHISELS

A wood chisel should always be held with the flat side or back of the chisel against the work for smoothing and finishing cuts. Whenever possible, it should not be pushed straight through an opening, but should be moved laterally at the same time that it is pushed forward. This method ensures a shearing cut, which with care, will produce a smooth and even surface even when the work is cross-grained. On rough work, use a hammer or mallet to drive the socket-type chisel.

On fine work, use your hand as the driving power on tang-type chisels. For rough cuts, the bevel edge of the chisel is held against the work. Whenever possible, other tools such as saws and planes should be used to remove as much of the waste as possible, and the chisel used for finishing purposes only.

There are a few basic precautions that you should observe at all times when using a chisel.

Figure 2-4-42.—Drill and auger bit sizes for wood screw.

44.120

Figure 2-4-43.—Types of wood countersinks.

a. Secure work so that it cannot move.

b. Keep both hands back of the cutting edge at all times.

c. Do not start a cut on a guideline. Start slightly away from it, so that there is a small amount of material to be removed by the finishing cuts.

d. When starting a cut, always chisel away from the guideline toward the waste wood, so that no splitting will occur at the edge.

e. Never cut towards yourself with a chisel.

f. Make the shavings thin, especially when finishing.

g. Examine the grain of the wood to see which way it runs. Cut with the grain. This severs the fibers and leaves the wood smooth. Cutting against the grain splits the wood and leaves it rough. This type of cut cannot be controlled.

5.11.1A

Figure 2-4-44.—Checking countersink portion of hole for size.

CHISELING HORIZONTALLY WITH THE GRAIN

To chisel horizontally with the grain, grasp the chisel handle in one hand with the thumb extended towards the blade (fig. 2-4-45). The cut is controlled by holding the blade firmly with the other hand, knuckles up and the hand well back of the cutting edge. The hand on the chisel handle is used to force the chisel into the wood. The other hand pressing downward on the chisel blade regulates the length and depth of the cut.

The chisel will cut more easily and leaves a smoother surface when the cutting edge is held at a slight diagonal to the direction of the

9240 ecse

Figure 2-4-45.—Chiseling horizontally across the grain.

cut, or is given a slight lateral sliding motion. This is done by holding the tool at a slight angle and moving it to one side as it is pushed forward, or by moving it slightly from left to right at the same time you push it forward. With cross-grained wood, it is necessary to work from both directions to avoid splitting the wood at the edges. Do not hurry. Cut only fine shavings. If thick shavings are cut, the tool may dig in and split off a piece of wood which was never intended to be removed.

CHISELING HORIZONTALLY ACROSS THE GRAIN

To chisel horizontally across the grain, hold the work so that it does not move. Remove most of the waste wood by using the chisel with the bevel held down. On light work, use hand pressure or light blows on the end of the chisel handle with the palm of the right hand. On heavy work, use a mallet. To avoid splitting at the edges, cut from each edge to the center and slightly upward so that the waste wood at the center is removed last (fig. 2-4-45). Make finishing cuts with the flat side of the chisel down. Never use a mallet when making finishing cuts, even on large work. One-hand pressure is all that is necessary to drive the chisel which is guided by the thumb and forefinger of the other hand. Finish cuts should also be made from each edge toward the center. Do not cut all the way across from one edge to the other or the far edge may split.

CHISELING DIAGONALLY ACROSS THE GRAIN

To chisel diagonally across the grain, such as making a straight slanting corner, remove as much waste wood as possible with a saw. (See fig. 2-4-46.) Hold the work so the guideline is horizontal. Use the chisel as in cutting horizontally with the grain. It is necessary to chisel with the grain and to hold the chisel so that the cutting edge is slightly diagonal to the direction of the cut.

Figure 2-4-46.—Chiseling diagonally across the grain.

CHAMFERING WITH A CHISEL

A chamfer is made by cutting off and flattening the sharp corner which exists between two surfaces which are at right angles to each other. A plain chamfer runs the full length of the edge and is usually made with a plane. A stopped chamfer does not run the full length of the edge. If a stopped chamfer is long enough, part of it can be planed and the ends finished with a chisel. A short stopped chamfer must be made entirely with a chisel. A chamfer is usually made symmetrically at 45°. Mark guidelines with a pencil; the guidelines for a 45° chamfer will be the same distance back from the edges on both surfaces of the wood (fig. 2-4-47).

9241

Figure 2-4-47.—Chamfering with a chisel.

NOTE: Do not use a marking gage, scratch awl, or knife to make guidelines, since they leave marks in the wood which are difficult to remove.

To cut a stopped chamfer, hold the chisel with the edge parallel to the slope of the chamfer and cut with the grain as in ordinary horizontal paring. Begin at the ends and work toward the center. The ends of a chamfer may be either flat or curved. If flat, use the chisel with the bevel up. If curved, keep the bevel down when cutting.

CHISELING A ROUND CORNER

To cut a round corner on the end of a piece of wood, first lay out the work and remove as much waste as possible with a saw (fig. 2-4-48). Use the chisel with the bevel side down to make a series of straight cuts tangent to the curve. Move chisel sideways across the work as it is moved forward. Finish curve by paring with the level side up. Convex curves are cut in the same manner as a round corner.

CUTTING A CONCAVE CURVE

When cutting a concave curve with a chisel, remove most of the waste wood with a coping saw or a compass saw. Smooth and finish the curve by chiseling (fig. 2-4-48) with the grain, holding the chisel with the bevel side down. Use one hand to hold the chisel against the work. Press down on the chisel with the other hand, and, at the same time, draw back on the handle to drive the cutting edge in a sweeping curve. Care must be used to take only light cuts or the work may become damaged.

Figure 2-4-48.—Chiseling corners and curves.

VERTICAL CHISELING

Vertical chiseling (fig. 2-4-49) means cutting at right angles to the surface of the wood which is horizontal. Usually it involves cutting across the wood fiber, as in chiseling out the ends of a mortise or making a gain on stopped dado joints. When vertically chiseling across the grain, a mallet may be used to drive the chisel. A mallet is necessary when chiseling hardwood. Use a shearing cut in cutting across the grain.

Figure 2-4-49.—Vertical chiseling.

9242

Always cut with the grain whenever possible, so that the waste wood will easily split away from the guidemarks. When chiseling on the ends of wood, remove as much waste wood as possible with a saw. Observe direction of grain and start to cut at an edge to avoid splitting the wood. Use a shearing cut and make the shavings thin. Thin shavings can be made without the use of a mallet. Grasp the handle of the chisel in one hand with the thumb pressing down on top of the handle, as shown in figure 2-4-49. Use the other hand to guide the tool, and to likewise supply some of the driving force if much pressure is required to do the job.

382-344 9243

PART II

Section 5

GRINDING AND FILING OPERATIONS

To keep hand tools in the best usable condition, cutting edges must be sharpened frequently and certain other tools trued or shaped for special purposes. Chisels, punches, drills, tinsnips, screwdrivers, and other hand tools are shaped or sharpened on an abrasive grinding wheel.

Grinding may be defined as the act of shaping or wearing down a surface or sharpening an edge by means of the cutting action of thousands of abrasive grains on the surface of the grinding wheel. Excessive grinding shortens the useful life of a tool.

A variety of grinding machines are in use in the Navy. Many of them are special machines used in tool and die making or machines used for other special purposes. The bench grinder, explained in part I, section 2, of this text, is the type of grinder most often found in general use in the Navy. Nearly all mechanical shops in shore installations or aboard ship will have a bench grinder.

ABRASIVE WHEELS

In any grinding operation, the selection of the proper abrasive wheel is of primary importance. Selection of the right wheel involves such factors as the material of the wheel, the material of the work, the amount of material to be removed from the work, and the nature of the finish required.

COMPOSITION

The abrasives are held together by a bonding agent. The strength with which the bonding agent holds the abrasive grains is known as the grade. Grade might also be described as the relative hardness of the wheel. The grade has considerable effect upon the grinding characteristics of a wheel. Spaces between grains (structure) also affect the result; if these spaces are too small, they may become clogged with metal particles from the work, and the wheel becomes "loaded." A loaded wheel will not grind properly and is likely to mar the work surface.

The standard markings given to grinding wheels by their manufacturers consist of a sequence of symbols. See fig. 2-5-1.

Figure 2-5-1.—Standard markings given to grinding wheels.

1. Abrasive type. The letter C is used for silicon carbide, and the letter A for aluminum oxide.

2. Grain size. The series 10, 12, 14, 16, 20, 24, 30, 36, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 220 is commonly used, with the low numbers representing coarse grain and the high ones a very fine grain size. A manufacturer may add a number and additional symbol to indicate a special grain combination for special purpose grinding.

3. Grade. This is indicated by a letter of the alphabet, A to Z—soft to hard.

4. Structure. Use of a structure symbol is optional. The general range is from 1 to 15,

9244

with the higher numbers indicating less density and wider grain spacing.

5. Bond type. These are indicated as follows: V, vitrified; E, shellac or elastic; S, silicate; R, rubber; B, resinoid; O, oxychloride.

6. Manufacturer's record. The symbol used here has reference to the manufacturer's factory records.

Although the markings given above are standardized, it is nevertheless a fact that wheels with identical markings may have different grinding actions if they are the output of different manufacturers. This is an important point to bear in mind when it becomes necessary to replace a wheel.

Typical wheels required for sharpening cutters and for other types of grinding are illustrated in figure 2-5-2. Reading from left to right the wheels are used as follows: (1) for cutting off Stellite, high-speed tool steel, tubing, etc.; (2) for grinding end mills, staggered tooth slotting cutters, reamers; (3) for cylindrical as well as surface grindings; (4) for face mills; (5) the straight cup, for flat forming tools such as lathe and planer cutter bits; (6) for internal grinding; (7) the flaring cup, for face and end mills, helical mills, slotting cutters, reamers; (8) for internal grinding; (9) the dished wheel, for gear cutters, formed cutters, taps.

STORAGE

Proper inspection and proper storage of grinding wheels are important. Wheels should be carefully inspected as soon as they are received, since there is always a possibility of the wheel being damaged in transit. To inspect for cracks, suspend the wheel and then tap it with some light implement, such as the wooden handle of a screwdriver. In doing this, make sure that the wheels are dry and free from sawdust. Vitrified and silicate wheels should emit a clear, metallic ring; wheels of other bonds give a different type of ring.

The detection of any cracks in a wheel is most important. When revolving at high speed, a cracked wheel may fly apart and cause serious injury.

Wheels should always be stored in a dry place. To prevent any shifting of the wheels, use pegs to support them in the storage racks.

DRESSING AN ABRASIVE WHEEL

An abrasive wheel often gets "out-of-round" and the peripheral surface gets out of shape. When this happens it is time to dress or true the wheel.

A dressing tool is provided for dressing an abrasive wheel. The wheel dresser shown in

Figure 2-5-2.—Types of grinding wheels.

figure 2-5-3 is the kind usually found in most shops and is very simple to use. Notice that the tool rest has been secured close to the wheel. The "feet" on the bottom of the dresser ride on the tool rest and the cutters touch the wheel.

Figure 2-5-3.—Dressing an abrasive wheel with a wheel dresser.

To dress the wheel, start the grinder and, when the wheel is up to speed, move the handle of the dresser ahead to bring the cutters into firm contact with the rotating wheel. Then move the dresser back and forth across the face of the wheel until the surface is clean and approximately square with the sides. This is an eye-hazardous operation. WEAR YOUR GOGGLES.

To dress the wheel with an abrasive stick, rest the stick on the tool rest as shown in figure 2-5-4. When the wheel comes up to speed, hold the stick against the rotating wheel firmly enough to remove the imbedded particles from the surface of the wheel. Move the stick back and forth across the face of the wheel until the surface is clean and approximately square with the sides. This also is an eye-hazardous operation. WEAR YOUR GOGGLES.

44.123

Figure 2-5-4.—Dressing an abrasive wheel with an abrasive stick.

GRINDING METAL STOCK

To grind a straight edge on metal stock (figure 2-5-5,) adjust the tool rest so that it just clears the wheel and is approximately at the center line of the wheel. Then, keeping the edge of the stock parallel with the center line of the grinder shaft, pass the stock across the face of the wheel. Grind across the entire width of the piece, using medium pressure which will keep the wheel cutting but will not appreciably decrease its speed. Grinding across the entire width of the piece and the wheel wears the wheel evenly and helps prevent overheating.

44.124

Figure 2-5-5.—Grinding a straight edge on metal stock.

To grind a bevel on an edge, (figure 2-5-6,) hold the stock as shown so that it is resting both on the wheel and on the edge of the tool rest. The edge being ground is away from the tool rest and therefore is not liable to get caught between the tool rest and the wheel. Pass the stock across the face of the wheel from left to right just as you do when grinding a square edge.

To grind a radius, set the tool rest at the center line of the wheel. With one hand, hold the end of the stock being ground so that you can

Figure 2-5-6.—Grinding a bevel on metal stock.

move it from left to right, across the face of the wheel, as shown by the small double-headed arrow in figure 2-5-7, and also hold it down firmly on the tool rest. With the other hand swing the arc shown by the longer curved double-headed arrow at the opposite end of the stock. The motion indicated by the curved arrow will produce the rounded edge on the stock. The travel indicated by the short straight double-headed arrow will prevent the wearing of a groove in the wheel which would have to be removed by dressing.

Figure 2-5-7.—Grinding a rounded edge on metal stock.

DRESSING TOOLS

The dressing of tools is an important part of hand tool maintenance. Dressing generally includes grinding the tools when they have become dulled or out of shape, or shaping the tools for specific jobs. There are some power grinders that are designed especially for tool grinding. However, these are not readily available in most small shops in the Navy. Therefore, most of the tool dressing operations must be done by holding the tool in your hand and grinding it with a bench grinder.

SHARPENING A CENTER PUNCH

To sharpen a center punch, cradle the end of the punch between the index finger and thumb of one hand, as shown in figure 2-5-8, resting that hand on the tool rest of the grinder. Move the punch into light contact with the rotating wheel of the grinder with the center line of the punch forming about a 45° angle with the face of the wheel. This will give the approximate 90° included angle required for a center punch. With the thumb and index finger of the other hand rotate the punch as shown by the directional arrow in figure 2-5-8. Keep the point cool by using only light pressure on the wheel and by frequently dipping the punch in a can of cooling water. Sharpen a prick-punch in the same

Figure 2-5-8.—Dressing a center punch with a bench grinder.

9247

way with the exception that, since the included angle should be 30° rather than 90°, the angle between the center line of this punch and the wheel should be about 15°.

DRESSING A SCREWDRIVER TIP

To see how to dress the tip of a screwdriver, refer to figure 2-5-9. Figure 2-5-9, parts A and B, are the front and side views of a common screwdriver; 2-5-9 C and 2-5-9 D are the front and side views of what is usually called an electrician's screwdriver.

Figure 2-5-9.—Shapes of screwdrivers when properly dressed.

To dress a common screwdriver, dress the sides so that the blade is symmetrical in shape. With electricians' screwdrivers, which are not forged at the tip, and therefore do not have the wide blade that the common screwdriver has, the width of the tip is determined by the diameter of the stock from which the shank is made.

Then, on both types, square off the end. Check the squareness of the end by resting the tip on the handle of a trysquare and moving the shank of the screwdriver close to the blade of the square. If the blade and the shank appear to be parallel, the tip is square. See figure 2-5-10.

On the common screwdriver, grind the faces of the blade so that they are parellel or nearly parallel at the tip as shown at B and D in figure 2-5-9. The thickness of the blade at the tip should be such that the tip will just enter the slot of the screws you intend to turn. With such

Figure 2-5-10.—Checking the squareness of the end of a screwdriver.

a tip thickness, and the sides parallel or nearly so, the screwdriver will have the least tendency to climb out of the screw slot when the screw is being turned home.

The electrician's screwdriver (or cabinet screwdriver) shown in 2-5-9 D has been ground by resting it flat against the grinding wheel. A 6-inch wheel produces about the right grind on a screwdriver used for small screws. Hold the blade high on the circumference of the wheel and rest the shank on the tool rest. See figure 2-5-11.

When grinding a screwdriver, do not let the tip get too hot or the temper will be drawn—overheating is discussed later in the section on sharpening metal cutting chisels.

Figure 2-5-11.—Grinding a screwdriver tip with a bench grinder.

SHARPENING TIN SNIPS

To sharpen tin snips on a grinder, open the snips as shown in figure 2-5-12, resting the blade on the tool rest. Hold the handle of the blade being ground level and the handle of the other blade level or slanting downward at whatever angle is necessary to grind the cutting edge to an included angle of 80° to 85°. Holding the blade lightly against the rotating wheel, move it from left to right across the face of the wheel. Sharpen first one blade of the snips and then the other. While sharpening one blade, be careful to keep the other blade from coming into contact with the side of the wheel. Sharpening tin snips requires close and careful attention; improper techniques may result in wrecking the snips or even in serious injury.

44.128

Figure 2-5-12.—Sharpening snips on a grinder.

GRINDING THE HEADS OF CHISELS

The mushroom head on the chisel shown in figure 2-5-13B is very dangerous. When struck with a hammer, chips may break off and injure you or others.

Remove the ragged edges of such a head by grinding them off. One way to do this is to hold the head against the wheel as shown in figure 2-5-14.

Turn the chisel with one hand as you apply pressure with the other. Grind across the entire face of the wheel to keep it flat. In figure 2-5-13 A you will see a properly ground head. Keep it that way by frequent grinding before it begins to mushroom as shown in figure 2-5-13 B.

29.9K

Figure 2-5-13.—Good and bad shaped chisel heads.

29.9L

Figure 2-5-14.—Grinding a chisel head with a bench grinder.

SHARPENING METAL CUTTING CHISELS

Metal cutting chisels, types of which are shown in figure 2-5-15, are sharpened by grinding. These chisels are designed to cut cold metal, and the cold chisel is the most common type. The general term "cold chisel" is often used when referring to any one of the chisels shown. The angle of 60°, shown on the cold chisel in figure 2-5-16, is for a general-use cold chisel. Increase this angle somewhat for cutting harder metals and decrease it for those that are softer.

To sharpen a metal-cutting chisel, hold the chisel to the wheel, resting it on the tool rest.

9249

Figure 2-5-15.—Types of points on metal cutting chisels.

Figure 2-5-16.—Proper angle for general use cold chisel.

(See figure 2-5-17.) Notice that the index finger, curved beneath the chisel, rides against the front edge of the tool rest. This affords good control of the chisel and will help you to grind a single, equal bevel on each side.

Figure 2-5-18 A shows a cold chisel ground with a slight radius, and figure 2-5-18 B shows a straight cutting edge. Both types of edges are used. The radius (fig. 2-5-18 A) is ground by swinging either end of the chisel slightly from left to right as the two faces of the cutting edge are being ground.

For shearing metal in a vise the chisel with the straight edge may be better. The chisel with the slight radius will probably work better when you are cutting metal on a flat plate.

Figure 2-5-17.—Sharpening a chisel with a grinder.

Figure 2-5-18.—Two common shapes of the cutting edges of cold chisels.

Notice, in figure 2-5-17, that a container of cooling water is near the tool rest. Let the chisel rest only lightly against the wheel when grinding. Less heat will be developed and, because the speed of the wheel is reduced only slightly, the air currents created by the wheel will have the maximum cooling effect. If the temperature of the cutting edge rises to the point where the metal begins to turn blue in color, the temper has been drawn, the cutting edge has been softened, and the edge will not stand up in use. The cutting edge will have to be rehardened, drawn to the proper temper (hardness), and the sharpening continued. As long as you can touch the cutting edge you are grinding with your bare hand and keep it there, you are in no danger of drawing the temper. Notice that it is the temperature of the cutting edge that is important. This means the very tip of the chisel where the bevel is being ground.

9250

The chisel at a point an inch or less from the cutting edge may be cool, while the cutting edge itself turns blue from overheating. Check this carefully while grinding.

SHARPENING TWIST DRILLS

The following requirements are of greatest importance in twist-drill grinding: (1) equal and correctly sized drill-point angles, (2) equal-length cutting lips, (3) correct clearance behind the cutting lips, and (4) correct chisel-edge angle. All four are equally important when grinding either a regular point (fig. 2-5-19) which is used for general purposes, or a flat point (fig. 2-5-20) which is used for drilling hard and tough materials.

Figure 2-5-19.—Specifications for grinding a regular point twist drill.

Figure 2-5-20.—Specifications for grinding a flat point twist drill.

Figure 2-5-21 shows what is meant by the two halves, A1 and A2, of the drill point angle, as well as the two equal-length cutting lips, L1 and L2.

Figure 2-5-21.—Halves and cutting lips of a twist drill.

Figure 2-5-22 shows a drill being checked during grinding. The drill-point gage is being held against the body of the drill and has been brought down to where the graduated edge of the gage is in contact with one cutting edge. In this way, both the drill-point angle and the length of the cutting edge (or lip) are checked at the same time. The process is repeated for the other side of the drill.

Figure 2-5-22.—Checking the drill point angle and cutting edge.

Lip clearance behind the cutting lip at the margin is determined by inspection. This means that you look at the drill point and approximate the lip-clearance angle (see figs. 2-5-19B and 2-5-20B), or compare it to the

9251

same angle that has been set up on a protractor. The lip-clearance angle is not necessarily a definite angle, but must be within certain limits. Notice that in figure 2-5-19 B it ranges from 8° to 12° and that the range given in figure 2-5-20 B is 6° to 9°, which overlaps the first range somewhat. Whatever angle in the range is used, however, lip clearance should be the same for both cutting lips of the drill.

There must be lip clearance behind the entire length of the cutting lip which extends from the margin of the drill to the chisel edge. This means that there must be "relief" behind the cutting lip along its entire length.

Whereas the lip clearance at the margin is measured by inspection, as shown in figures 2-5-19B and 2-5-20B, lip clearance at the other end of the cutting lip (at the chisel edge) is measured by inspection of the chisel-edge angle. The clearance behind the cutting lip at the chisel edge is greater than at the margin. The chisel-edge angle indicates how much clearance there is behind the cutting lip where it meets the chisel edge. As you grind more clearance behind the cutting lip near the chisel edge, the chisel-edge angle will get larger.

For a regular point, the chisel-edge angle can vary from 120° to 135° and the lip-clearance angle can vary from 8° to 12°. See figure 2-5-19 again.

For a flat point, the chisel-edge angle can vary from 115° to 125° and the lip-clearance angle from 6° to 9°. See figure 2-5-20 again. The greater the angles are in both cases, the more lip clearance there will be, and vice versa.

When lip clearance is being "ground into" a drill, inspection of the lip-clearance angle (shown at B in figs. 2-5-19 and 2-5-20) and of the chisel-point angle (shown at C in figs. 2-5-19 and 2-5-20) will be your guide to the amount of clearance you have ground into the drill behind the cutting lip along its entire length. The greater these angles are, the more clearance there will be behind their respective ends of the cutting lip. Too much lip clearance, which occurs when both the lip-clearance angle and the chisel-edge angle exceed their top limits, weakens the cutting edge or lip by removing too much metal directly behind it. Too little or no lip clearance, prevents the cutting edge from producing a chip, or cutting, and the drill will not drill a hole.

To SHARPEN TWIST DRILLS, first get the grinder ready. If necessary, dress the face of the wheel so that it is clean, a true circle, and square with the sides. Before starting the grinder, readjust the tool rest to 1/16" or less from the face of the wheel. This is an important safety measure which will help keep work from wedging between the tool rest and the face of the wheel.

Figure 2-5-23.—Grinding a twist drill with a grinder.

Now, start the grinder and when it has come up to speed, hold the twist drill as shown in figure 2-5-23A, which is a top view of the first step in grinding a drill. The axis of the drill, in the first step, should make an angle of about 59° (half of the drill-point angle in fig. 2-5-23A) with the face of the wheel. The cutting lip should be horizontal.

Figure 2-5-24 is an actual photograph, side view, of the same drill position which is shown in figure 2-5-23A.

The actual grinding of the drill point consists of three definite motions of the shank of the drill while the point is held lightly against the rotating wheel. These three motions are: (1) to the left, (2) clockwise rotation, (3) downward.

Figure 2-5-23 shows the motion to the left in three views as the angle between the face of the wheel and the drill decreases from about 59° to about 50°.

In figure 2-5-23 the clockwise rotation is indicated by the advance of the rotation arrows in A, B, and C. Rotation is also pictured by the change in position of the cutting lip as well as that of the tang.

Because figure 2-5-23 is a top view, the third (downward) motion is not noticeable. However, all three motions are apparent when an actual photograph of the final position of the

9252

44.20Y

Figure 2-5-24.—Grinding a twist drill with a grinder.

drill in figure 2-5-25 is compared to the initial position in figure 2-5-24. All three motions taking place at the same time combine to produce the important requirements mentioned before (1) equal and correctly sized drill-point angles (2) equal-length cutting lips, (3) correct clearance behind the cutting lips, and (4) correct chisel-edge angle. Checking by means of a drill-point gage, figure 2-5-22, and by inspection will show when these four requirements have been met.

44.132

Figure 2-5-25.—Grinding a twist drill with a grinder.

SHARPENING A TWIST DRILL FOR DRILLING BRASS

To grind a drill for drilling brass (fig. 2-5-26 A) hold the cutting lip against the right side of the wheel as shown in figure 2-5-26 B. Grinding the flute slightly flat, in line with the axis of the drill, greatly reduces the included angle of the cutting lip. This will give the drill a scraping action, necessary for brass, rather than the cutting action used for steel. This scraping action will prevent the tendency, that invariably occurs with drills not ground for brass, to stick in the hole being drilled. This sticking is troublesome especially when drilling through a pilot hole.

40.20AA

Figure 2-5-26.—Grinding a twist drill for brass.

THINNING THE WEB OF A TWIST DRILL

Repeated sharpening, which shortens the drill, or the fact that the remaining length of a broken drill has been resharpened, results in an increase in the web thickness at the point. This may require web thinning. Correct web thinning, when it becomes necessary, is important for satisfactory drilling.

To thin the web of a drill, hold the drill lightly to the face of a round-faced wheel, as shown in figure 2-5-27A, thinning the web for a short distance behind the cutting lip and into the flutes. This is shown in figure 2-5-27B. Notice that the cutting lip is actually (but only slightly) ground back, reducing its included angle only a very little and not enough to affect the operation of the drill.

9253

Figure 2-5-27.—Thinning the web of a twist drill.

SHARPENING TWIST DRILL BY MACHINE

Sharpening a twist drill by hand is a skill that is mastered only after much practice and careful attention to the details. Therefore, whenever possible, use a tool grinder in which the drills can be properly positioned, clamped in place and set with precision for the various angles. This machine grinding (fig. 2-5-28) will enable you to sharpen the drills accurately. As a result, they will last longer and will produce more accurate holes.

Whether you are sharpening a drill by hand or by machine, it is very necessary that the temperature at the point be kept down. As the point gets hot, it approaches the temperature at which the temper of the steel will be drawn. To draw the temper means to remove the hardness.

Figure 2-5-28.—Sharpening a twist drill with a tool grinder.

Keep the point cool enough to be held in your bare hand. Do this by making a few light passes over the grinding wheel, take a few seconds to let the point cool and repeat alternate grinding and cooling. With only slight pressure against the wheel, less heat is developed and the speed of the wheel is maintained. Wheel speed creates air currents which also help to keep the point cool.

Once you notice the appearance of a blue temper color at the point, it is too late. You have drawn the temper and the steel is now too soft to hold a cutting edge. Then the only thing you can do is to continue the sharpening process, first one lip and then the other, until you have finally ground away the soft tip of the drill. This means that you must grind away all that portion of the tip which is blue. As the blue color indicates softness throughout the entire point of the drill, and not only on the blue surface, resharpening must be continued until all of the blue-colored metal has been ground away.

This operation must be done very slowly and carefully, keeping the point cool to prevent continual bluing of the metal.

FILING OPERATIONS

Using a file is an operation that is nearly indispensable when working with metal. Filing is done when a small amount of metal is to be removed. To better understand this section, you may need to review the section on "files" in part I, section 1, of this course.

When you have finished using a file it may be necessary to use an abrasive cloth or paper to finish the product. Whether this is necessary depends on how fine a finish you want on the work.

FILING MILD STEEL

Figure 2-5-29 shows a piece of mild steel being crossfiled. This means that the file is being moved across the surface of the work in approximately a crosswise direction. For good results, keep your feet spread apart to steady yourself as you file with slow full-length steady strokes. The file cuts as you push it—ease up on the return stroke to keep from dulling the teeth. Keep your file clean.

Figure 2-5-30 shows the alternate positions of the file when an exceptionally flat surface is required. Using either one position or the

9254

1.20A

Figure 2-5-29.—Crossfiling a piece of mild steel.

1.20B

Figure 2-5-30.—Alternating positions when filing.

other first, file across the entire length of the stock. Repeat this until the entire surface has had metal removed by the file. Then, using the other position, file across the entire length of the stock again. Because the teeth of the file pass over the surface of the stock from two directions, the high spots and low spots will readily be visible after filing in both positions. Continue filing first in one position or direction and then the other until the surface has been filed flat. Test the flatness with a straight edge or with prussian blue and a surface plate.

Draw filing produces a finer surface finish and usually a flatter surface than crossfiling. Small parts, as shown in figure 2-5-31, are best held in a vise. Hold the file as shown in the figure; notice that the arrow indicates that the cutting stroke is away from you when the handle of the file is held in the right hand. If the handle is held in the left hand, the cutting stroke will be toward you.

Lift the file away from the surface of the work on the return stroke. When draw filing will no longer improve the surface texture, wrap a piece of abrasive cloth around the file and polish the surface as shown in figure 2-5-32.

1.20C

Figure 2-5-31.—Drawfiling a small part.

Always keep the file clean, whether you're filing mild steel or other metals. Use chalk liberally when filing nonferrous metals.

POLISHING A FLAT METAL SURFACE

When polishing a flat metal surface, first draw file the surface as shown in fig. 2-5-31.

Then, when the best possible draw filed surface has been obtained, proceed with abrasive cloth, often called emery cloth. Select a grade of cloth suited to the draw filing. If the draw filing was well done only a fine cloth will be needed to do the polishing.

If your cloth is in a roll, and the job you are polishing is the size that would be held in a vise, tear off a 6" or 8" length of the 1" or 2" width. If you are using sheets of abrasive cloth, tear off a strip from the long edge of the 8" by 11" sheet.

Wrap the cloth around the file (fig. 2-5-32) and hold the file as you would for draw filing.

1.20D

Figure 2-5-32.—Polishing metal with abrasive cloth wrapped around a file.

9255

Hold the end of the cloth in place with your thumb. In polishing, use a double stroke with pressure on both the forward and the backward strokes. Note that this is different from the drawfiling stroke in which you cut with the file in only one direction. Use lubricating oil on the surface being polished.

When further polishing does not appear to improve the surface, you are ready to use the next finer grade of cloth. Before changing to the finer grade, however, reverse the cloth so that its back is toward the surface being polished.

Work the reversed cloth back and forth in the abrasive-laden oil as an intermediate step between grades of abrasive cloth. Then, with the solvent available in your shop, clean the job thoroughly before proceeding with the next finer grade of cloth. Careful cleaning between grades helps to ensure freedom from scratches.

For the final polish, use a strip of crocus cloth—first the face and then the back—with plenty of oil. When polishing is complete, again carefully clean the job with a solvent and protect it, with oil or other means, from rusting.

Figure 2-5-33A shows another way to polish in which the abrasive cloth is wrapped around a block of wood. In figure 2-5-33B, the cloth has simply been folded to form a pad from which a worn, dull surface can be removed by simply tearing it off to expose a new surface.

Figure 2-5-33.—Alternate methods for polishing metal surfaces.

FILING ROUND METAL STOCK

Figure 2-5-34 shows that, as a file is passed over the surface of round work, its angle with the work is changed. This results in a rocking motion of the file as it passes over the work. This rocking motion permits all the teeth on the file to make contact and cut as they pass over the work's surface, thus tending to keep the file much cleaner and thereby doing better work.

Figure 2-5-34.—Filing round metal stock.

POLISHING ROUND METAL STOCK

In figure 2-5-35, a piece of round stock is being polished with a strip of abrasive cloth which is "seesawed" back and forth as it is guided over the surface being polished.

Remember that the selection of grades of abrasive cloth, the application of oil, and the cleaning between grades, applies to polishing regardless of how the cloth is held or used.

Figure 2-5-35.—Polishing round metal stock.

TESTING METAL FOR HARDNESS

A quick and practical test for hardness can be made with an ordinary mill file. Hold a piece of stock in a vise, or firmly against the edge of the bench, and pass the file over its surface, preferably at an edge or at a corner. If the file will take hold and cut the surface of the metal,

it indicates that the metal is softer than the file itself and can therefore be filed, drilled or cut with a hacksaw. If the file seems to slide over the surface of the metal, then its teeth are not cutting, and the metal cannot be drilled with twist drills or cut with a hacksaw. In this case, other methods of cutting will have to be employed. Among these methods are grinding, abrasive wheel cutting, and torch cutting.

USING SHARPENING STONES

Sharpening stones are often used for final dressing of edged tools. When a tool is ground with a grinder there is often a wire edge that should be removed. This can be done by honing the edge of the tool with a sharpening stone. There are many times when the sharp edge of a tool is dulled but is not damaged to the extent that it needs grinding. In these cases honing with a sharpening stone is all that is necessary to restore the keen edge to the tool. Do not grind a tool unless it is necessary, as it will wear away metal unnecessarily and may distort the original shape of the tool.

Figure 2-5-36.—Sharpening a woodworker's chisel.

SHARPENING A CHISEL ON A SHARPENING STONE

To sharpen a wood chisel with a sharpening stone, use a common oilstone that has coarse grit on one side and fine grit on the other. (See fig. 2-5-36.) Make sure the stone is firmly held so that it cannot move. Cover the stone with a light machine oil so that the fine particles of steel ground off will float and thus prevent the stone from clogging.

Hold the chisel in one hand with the bevel flat against the coarse side of the stone. Use the fingers of your other hand to steady the chisel and hold it down against the stone. Using smooth even strokes, rub the chisel back and forth parallel to the surface of the stone (fig. 2-5-36). The entire surface of the stone should be used to avoid wearing a hollow in the center of the stone. Do not rock the blade. The angle of the blade with the stone must remain constant during the whetting process.

After a few strokes, a burr, wire edge, or feather edge is produced. To remove the burr, first take a few strokes with the flat side of the chisel held flat on the fine grit side of the stone. Be careful not to raise the chisel even slightly; avoid putting the slightest bevel on the flat side, for then the chisel must be ground until the bevel is removed.

After whetting the flat side on the fine grit side of the stone, turn the chisel over and place the bevel side down and hold it at the same angle as used when whetting on the coarse side of the stone. Take two or three light strokes to remove the burr.

To test the sharpness of the cutting edge, hold the chisel where a good light will shine on the cutting edge. A keen edge does not reflect light in any position. If there are no shiny or white spots it is a good edge.

SHARPENING A POCKET KNIFE ON A SHARPENING STONE

Most pocket knives may be sharpened on a medium or fine grade sharpening stone with a few drops of oil spread on the surface. Hold the handle of the knife in one hand and place the blade across the stone. Press down with the fingers of the other hand and stroke the blade following a circular motion as shown in figure 2-5-37.

9257

Figure 2-5-37.—Sharpening a pocket knife.

After several strokes, reverse blade and stroke opposite side, following the same type of motion. Use a light even pressure. A thin blade overheats quickly and can lose its temper. The wire edge or burr that may be left on a knife blade after whetting may be removed by stropping both sides on a soft wood block, canvas or leather.

NATIONAL BUREAU OF STANDARDS-1963-A

PART II

Section 6

METAL CUTTING OPERATIONS

The cutting of metal can, in some instances, be a simple operation where accuracy is not important. However, in most cases the cutting of metal is an important and precise job. A large number of tools, both power and hand, have been designed to make metal-cutting operations speedy, economical, and accurate in all kinds of material.

As you advance in your Navy career you will find that there are many special tools designed to do specific jobs. This is true in all ratings but especially true when the rating requires working with metal. Only the skills that require the use of common and versatile metal cutting tools will be discussed in this section.

METAL CUTTING WITH CHISELS

One of the earliest methods of shaping a piece of metal was to chip away the unwanted material with a hammer and chisel. This practice is still common for jobs that are done at the workbench, and where it is not practical to do the work on a machine. The different shapes and sizes of metal cutting chisels were discussed, in part I, section 1, of this course.

CUTTING METAL ON A FLAT SURFACE

To cut metal on a flat plate, place the metal on a heavy bench plate or similar surface that will serve as backing for the hammer blows. Hold the cold chisel firmly in the cut and slanting slightly away from the direction in which it is cutting. (See fig. 2-6-1). Advance the chisel along the scrap side of the layout line after each hammer blow. Cut through on the first blow for the lighter gages of metal. Heavier gages will require a second or third blow.

Figure 2-6-1.—Cutting metal on a flat surface.

CHIPPING METAL WITH A CHISEL.

"Chipping" is a term applied to the removal of metal with the cold chisel and hammer. The degree of accuracy required varies.

Secure the work in a vise with a block under the work to prevent it from slipping. Place canvas or some other type of chipping guard in front of the work to keep flying chips from hitting men working in front of you. Wear goggles to protect your eyes.

For most ordinary chipping with a 3/4-inch chisel, use a 1-pound hammer. Use a lighter hammer for a smaller chisel. Always use a well-sharpened chisel.

282-344 O - 67 - 11

9259

Grasp the chisel with one hand, holding the cutting edge to the work and striking the other end of the chisel with the hammer. Keep your eyes on the cutting edge of the chisel to watch the progress of the work. The bevel side of the chisel is the guiding surface, and is held at a very slight angle with the finished part of the work which the cutting edge is touching. Raising or lowering the shank of the chisel increases or decreases the inclination of the guiding bevel and causes the chisel to take a heavier or lighter cut.

To start the chip, the angle 1 in figure 2-6-2A must be great enough to cause the cutting edge to enter the surface of the metal. After the cut has been started, and the desired depth reached, decrease this angle, as shown at 2 in figure 2-6-2B, as the chisel advances or cuts. If you want to decrease the depth of the cut, decrease the angle as shown at 3 in figure 2-6-2C. Notice here that the chisel is riding on the heel of the bevel, causing the cutting edge to "climb out" of the cut.

When chipping wrought iron or steel, wipe the edge of the chisel with an oil-saturated cloth frequently. This will lubricate the contacting surfaces and preserve the cutting edge of the chisel.

After every two or three blows, draw the chisel back slightly from the chip. This tends to ease your muscles and gives you better control over the job.

When chipping case metal, begin at the ends and chip toward the center to keep from breaking corners and edges. Take cuts from 1/16 to 1/32 inch. Leave enough stock so that the surfaces may be finished with a file.

Figure 2-6-2.—Chipping metal with a chisel.

CUTTING WIRE OR ROUND STOCK

When a suitable hacksaw is not available to cut round stock, the chisel may be used.

Mark off a guideline on the stock and place the work on the top face of an anvil or other suitable working surface. Place the cutting edge of the chisel on the mark in a vertical position and lightly strike the chisel with a hammer. Check the chisel mark for the desired cut. Continue to strike the chisel until the cut is made. The last few blows of the hammer should be made lightly to avoid damage to the anvil, supporting surface, or to the chisel.

Heavy stock is cut in the same manner except that the cut is made halfway through the stock; the work is then turned over and the cut finished from the opposite side.

SHEARING METAL IN A VISE

To shear metal in a vise, hold the metal in the bare vise jaws (fig. 2-6-3) in order to provide a shearing action between the rear jaw of

Figure 2-6-3.—Shearing metal with a chisel.

9260

the vise and the cold chisel. Advance the chisel after each blow so that the cutting action takes place in about the center of the cutting edge of the cold chisel. If you are shearing to a line, hold the metal so that the line is just concealed by the front jaw of the vise. After cutting, it will then be visible along the sheared edge to serve as a guide for grinding or filing.

To cut an internal hole by shearing, hold the metal in the vise as you do for plain shearing. Notice that the cut is being made from a to b in figure 2-6-4A, and that the cutting has stretched the metal at the jaws of the vise. When ab has been cut, hold the metal in the vise along the other lines and cut bc, cd, and da. (See fig. 2-6-4B.)

On the second cut, from b to c, as well as on the next two cuts, the metal will curl back and away from the cut as the cutting proceeds. At the end of the fourth cut, to a point a, which was also the starting point, the scrap will fall away. Then raise the metal in the vise just enough to see the layout line in the clear and dress each sheared edge with a file down to the line. See figure 2-6-4C.

Figure 2-6-4.—Shearing an internal hole in sheet metal.

CUTTING OFF A RIVET OR BOLT HEAD

To cut off a rivet or bolt head with a chisel, hold the job in a heavy vise or secure it some other way so that the work will not move. (See fig. 2-6-5A.) Hold the cold chisel with one face of the bevel flat on the surface of the job. Strike the head of the chisel with the hammer as you loosely hold and guide the chisel.

Figure 2-6-5.—Cutting off a rivet head with a chisel.

To cut off a rivet head with a cape chisel, select a chisel of about the same size as the diameter of the rivet. Cut through the center of the rivet head, holding one face of the bevel flat on the surface of the job, and then sever the center of the head from the shank or body, as shown in figure 2-6-5B.

To cut off a rivet head with a side cutting chisel, commonly called a rivet buster, place the chisel nearly flat on the surface of the work with its single bevel upwards. (The main difference between a rivet buster and a common cold chisel is that the rivet buster has only one bevel.) Drive the cutting edge under the edge of the rivet head just as you would if you were using a cold chisel. (See fig. 2-6-6A). Notice in figure 2-6-6B that the cutting edge of the chisel has a slight radius which will tend to prevent the corners from cutting undesirable grooves in the surface of the work.

To remove a rivet head (fig. 2-6-7) when there is not room enough to swing a hammer with sufficient force to cut the rivet, first drill a hole about the size of the body of the rivet in and almost to the bottom of the rivet head. Then cut off the head with a cold chisel.

9261

Figure 2-6-6.—Cutting off a rivet head with a side cutting chisel.

Figure 2-6-7.—Removing a rivet head in a hard to reach position.

CUTTING A GROOVE IN METAL

To cut a groove in metal (fig. 2-6-8), select a half-round chisel the size of the required groove. For small grooves, a round-nose chisel may be used.

As the chisel is driven forward, it will roll a chip ahead of the cutting edge (fig. 2-6-8), cutting a groove in the surface. You can control the depth of the groove by raising or lowering the handle of the chisel. When the handle is lowered, the chisel will tend to "ride out" of the cut on the heel—the part of the chisel just behind the cutting edge.

Figure 2-6-8.—Cutting a groove in metal.

CUTTING SHEET METAL WITH SNIPS

To cut large holes in the lighter gages of sheet metal, start the cut by punching or otherwise making a hole in the center of the area to be cut out. With an aviation snips, as shown in figure 2-6-9, or some other narrow-bladed snips, make a spiral cut from the starting hole out toward the scribed circle and continue cutting until the scrap falls away.

Figure 2-6-9.—Cutting an inside hole with snips.

To cut a disk in the lighter gages of sheet metal, use a combination snips or a straight blade snips as shown in figure 2-6-10. First, cut away any surplus material outside of the scribed circle leaving only a narrow piece to be removed by the final cut. Make the final cut just outside of the layout line. This will permit you to see the scribed line while you are cutting and will cause the scrap to curl up below the blade of the snips where it will be out of the way while the complete cut is being made.

To make straight cuts, place the sheet metal on a bench with the marked guideline over the edge of the bench and hold the sheet down with one hand. With the other hand hold the snips so that the flat sides of the blades are at right angles to the surface of the work. If the blades are not at right angles to the surface of the work, the edges of the cut will be slightly bent and burred. The bench edge will also act as a guide when cutting with the snips. The snips will force the scrap metal down so that it does not interfere with cutting. Any of the hand snips may be used for straight cuts. When notches are too narrow to be cut out with a pair of snips, make the side cuts with the snips and cut the base of the notch with a cold chisel.

9262

11.252X

Figure 2-6-10.—Cutting a disk out of sheet metal.

CUTTING HOLES IN METAL WITH PUNCHES

When using a hollow punch to cut holes in metal you should make layout lines on the stock metal. Use a center punch to mark the center of the hole. Scribe the desired circle with a pair of dividers.

When using either a hollow punch (fig. 2-6-11A) or a solid punch, (fig. 2-6-11B), place the stock sheet metal on top of a lead or wooden block. Strike the punch with a hammer to drive it through the metal. The lead or wood block keeps the punch from being damaged.

DRILLING HOLES IN METAL

Before drilling any material, even wood, it is a good idea to center-punch the exact location of the hole. This forms a seat for the drill point and assures accuracy. It is especially important in metal since, without the mark, the drill could "walk off" before it begins to cut into the material.

44.139

Figure 2-6-11.—Cutting holes in metal with punches.

When drilling sheet metal, place the sheet on a flat surface to prevent the pressure you apply from buckling the sheet. The material you are drilling must be securely clamped.

Always apply pressure on a line which goes straight through the axis of the twist drill. Keep the drill steady and apply enough pressure to keep it cutting. Too much pressure will overload the motor; too little pressure will merely cause the drill to "polish" instead of cut. This will quickly dull the cutting edges of the drill. You will know the pressure is correct when the drill bites continuously without loading the drill motor.

Once you have lined up the drill with the hole, keep the drill straight. Side pressure or swaying off the line will enlarge the hole and can break the twist drill.

When drilling large holes, do it in stages, especially if you are using a low-power drill. A pilot hole is a good idea, since it serves as a guide for the larger drill and helps to increase accuracy. Above all, keep the drills sharp.

It is necessary to use a cutting oil to lubricate and cool the drill when drilling steel and wrought iron. Cast iron, aluminum, brass and other metals may be drilled dry, although at high drilling speeds it is advisable to use some medium to cool these metals. Compressed air may be used for cast iron; kerosene for aluminum; oleic acid for copper; sulfurized mineral oil for Monel metal; and water, lard, or soluble oil and soda water for ferrous metals (the soda water reduces heat, overcomes rust, and improves the finish).

HOLDING WORK FOR DRILLING

Most work is held for drilling by some mechanical means such as a clamp, vise, or pliers. When drilling small holes in fairly large pieces of work, it is permissible to hold the work with the bare hands to keep it from turning when the drill begins to cut. Under these conditions, a small drill will break in case it grabs, and the work will not be dangerously spun around at drill speed.

To drill small holes in small pieces with a hand drill or an electric drill, hold the work in

9263

a vise so that the axis of the drill is horizontal. See figure 2-6-12A and B. This position provides better control of the drilling and will tend to ensure a hole which will be square with the surface of the work.

Figure 2-6-12.—Holding small pieces in a vise for drilling.

To drill small holes in small pieces with a drill press, hold the work either with a monkey wrench (fig. 2-6-13), in a drill press vise (fig. 2-6-14), with pliers or locking pliers (fig. 2-6-15), or between V blocks (fig. 2-6-16).

Figure 2-6-13.—Holding work with a monkey wrench.

To drill holes in the end of round stock, place the stock in one of the V-grooves in the stationary jaw of the drill vise as shown in figure 2-6-17. These V-grooves will hold the work so that it is square with the table of the drill press. The drilled hole will then be parallel with the axis of the round stock.

To drill small holes in long pieces (fig. 2-6-18), hold the stock in your left hand and feed the drill with your right hand. Drill over the center hole in the drill press table, if it has one, or place the stock on a flat piece of wood to protect the table. Reduce the feed pressure as

Figure 2-6-14.—Holding work with a drill press vise.

Figure 2-6-15.—Holding work with a pair of locking pliers.

Figure 2-6-16.—Holding work in V-blocks.

44.141

Figure 2-6-17.—Holding work to drill holes in end of round stock.

44.140A

Figure 2-6-18.—Holding a long piece for drilling a small hole.

the drill reaches the end of its cut to prevent drill breakage.

To drill large holes in large pieces, hold the work by using a step block and clamps, some types of which are shown in figure 2-6-19. Often pieces of metal of the proper thickness are substituted for a step block. A piece of metal with a hole drilled near one end makes a satisfactory substitute for a clamp.

To hold work with clamps and step blocks, the gooseneck clamp may be used, as in figure 2-6-20, to provide clearance for such obstructions as the nut below the overhang on the job shown. Notice that the body of the clamp is approximately parallel with the surface of the drill press table and that the bolt is held close

11.15X

Figure 2-6-19.—Step block and clamps.

28.231

Figure 2-6-20.—Holding work with step block and clamp for drilling.

to the work rather than close to the step block. This provides the most favorable mechanical advantage. Usually two or more clamps are used on each setup.

To hold thin metal for drilling, place it on a block of wood to provide support directly beneath the hole. This will help minimize drill breakage when the feed pressure is applied. Then secure the C-clamp as shown in figure 2-6-21, and drill through the metal and into the wood. Stop drilling when wood chips appear so as not to damage the drill press table. Some tables have no center hole, or, if there is a center hole, it may not be lined up directly below the drill.

SPEED AND FEED FOR DRILLING

The SPEED of a drill is the distance the drill would roll if it were placed on its side and rolled at a given rpm for 1 minute. This speed is usually expressed in feet per minute (fpm). The correct cutting speed for a job depends upon the

44.140B

Figure 2-6-21.—Holding thin gage metal for drilling.

9265

degree of hardness of the metal, the impurities in the metal, and the type of drill used. The following speeds are recommended when using high-speed drills.

Alloy steel	50-70 fpm
Machine steel	70-100 fpm
Cast iron	70-150 fpm
Brass	200-300 fpm

Carbon steel drills should be run at approximately one-half the speeds given above. With practice, you will be able to determine for yourself the correct speed for each piece of work.

The speed of the drill press is given in rpm. Tables giving the proper rpm at which to run a drill press for a particular metal are usually available in the machine shop, or they may be found in machinists' handbooks.

The FEED of a drill is the rate of entry into the work during each revolution. Feed is expressed in thousandths of an inch per revolution. In general, the larger the drill, the heavier the feed that may be used.

COUNTERBORING HOLES IN METAL

Counterboring is the operation of boring a second hole, larger in diameter than the first but concentric with it. A tool known as a counterbore is used for this operation. (See fig. 2-6-22.) The small diameter on the end of the tool, known as a pilot, keeps the counterbore concentric with the original hole. Pilots of different sizes are interchangeable to fit various sizes of holes.

Counterbores are also used for spot facing. In this operation, usually performed on castings, the objective is to remove enough material to provide a flat surface around a hole to accommodate the head of a bolt, nut or screw.

Counterbores for screw holes in metal are available in the usual twist drill sizes from 1/4" to 3", in either taper or straight shanks. They are generally made in sets, and a set may include counterbores ranging in size from 1/4 inch to 1 inch by 16ths. Pilots will be included which increase in size by 32ds in the smaller sizes and by 16ths in the larger sizes. Because the pilots are removable, various combinations of counterbores and pilots are possible. In figure 2-6-23A and B are the same size counterbores with pilots of different sizes as indicated. B and C are the same size pilots with counterbores of different sizes as indicated.

Figure 2-6-22.—Counterboring tool with pilot.

Figure 2-6-23.—Various combinations of counterbores and pilots.

A counterbore can be used to counterbore, or to spot-face, or to drill holes in metal which is too thin to drill with a twist drill.

Figure 2-6-24 is a drawing of a counterbored hole for a 3/8" fillister head or an internal chucking head screw. Here the pilot size is 3/8", which is the body hole size, and the body size of the counterbore is equal to the nominal diameter of the head of the screw.

Figure 2-6-24.—Drawing of a counterbored hole for a filluster head screw.

In figure 2-6-25A, the surface of the casting has been spot-faced to make it clean and square with the hole and seat the head of the cap screw properly.

To spot-face the surface of a casting, select a counterbore that will be larger than the greatest diameter of the head of the cap screw. This is necessary so that the entire bottom of the

screw head will rest on the spot-faced surface. See figure 2-6-25B. Then select a pilot the size of the screw body hole, insert it in the counterbore, and proceed with the counterboring until the seating surface is cleaned up.

Figure 2-6-25.—Spot facing a surface on a casting.

Figure 2-6-26.—Counterboring a hole in thin metal.

Figure 2-6-26 shows how a piloted counterbore is used to bore holes in thin metal. Secure the stock over a block of wood on the drill press table, as shown in figure 2-6-26A, and drill the pilot hole through the metal and into the wood. Then follow up with the counterbore, using a pilot to fit the pilot hole, and bore with the counterbore until the larger hole has also been bored through the metal and into the wood. (See fig. 2-6-26B.)

THREADS AND THREAD CUTTING

Threads are helical ridges cut into screws, nuts, bolts, or the walls of a hole, so that the action of turning the screw, nut, or bolt gives it endwise as well as rotary motion.

There are many types of threads, each designed for a specific type of work. The most common type of bolt threads in use today, however, is the American National form of threads of which there are two series: coarse thread series and fine thread series. The fine threads are of the same general shape as the coarse ones, but they are smaller and there are more of them per inch. Nuts with fine threads may be drawn up tighter than those with coarse threads, and they will not shake loose so easily.

Machine screw threads are of the same general shape as bolt threads, but they are much smaller. Machine screws are used in small machines and apparatus such as small motors, electric fans, and carburetors.

Pipe threads are used on pipe and pipe-and-tubing connections on engines, motors, and other machines. Pipe threads have a taper of 1/16 inch per inch of length. Since the threaded end of a pipe is tapered, the farther it is screwed into a fitting, the tighter the joint becomes. This makes it possible to make a tight joint without having any tension or end pull on the pipe. Since bolt and machine threads are straight they do not tighten until they are drawn up against the part being held.

Because of the system of indicating pipe sizes, pipe threads are much larger than the corresponding size of bolt threads. The size of pipe is designated by its inside diameter. A 1/2-in. bolt die cuts threads on the outside of a rod or bolt whose outside diameter is 1/2-in.; a 1/2-in. pipe die cuts threads on the outside of a pipe whose inside diameter is 1/2-inch. The pipe die, therefore, is much larger.

It is common practice to indicate the size of a bolt thread by two numbers, the first being the diameter of the bolt and the second the number of threads per inch. For example, a 3/8—16 thread would be for a 3/8-in. bolt which has 16 threads per inch. The size of a machine-screw thread, or a tap or die for cutting it, is designated by two numbers in the same manner as bolt threads, the first number being the size of the screw and the second the number of threads per inch. For example, an 8—32 thread is for a No. 8 screw which has 32 threads per inch.

DETERMINING THE PROPER SIZE TAP DRILL FOR PARTICULAR TAPS

If a threaded hole is to be made in a piece of metal, a hole of suitable size must first be drilled. The hole must be somewhat smaller than the size of the bolt to be screwed into it, usually 1/16 in. smaller for bolts 1/4 to 1/2 in. in size.

9267

The best method to determine the exact size of tap drill to use is to refer to the American National Form Threads chart in appendix II of this course. A chart similar to this generally is included with a set of taps and dies.

Figure 2-6-27.—A working drawing for tapping and cutting threads.

The working drawing shown in figure 2-6-27, specifies a 1/2 in. 13 National Coarse (NC) thread to be tapped in a through hole in one part (1/2 in. deep hole in 1/2 in. stock). The same thread is to be tapped in a blind hole in another part (3/4 in. deep hole in 1 in. stock). The 1/2 in. round stock is to be threaded with this same thread to fit the tapped holes.

Refer to the chart in appendix II and run down the first two columns until you locate 1/2—13 N.C. Follow this line to the right until you come to the tap drill size, 27/64 in. which will produce approximately a 75 percent full thread. Use the 27/64 in. drill to drill a through hole in the 1/2 in. block and a hole 3/4 in. deep in the 1-in. block as required by the working drawing.

When the tap hole is the right size, it is a little larger than the root diameter of the tap as shown in figure 2-6-28. The tap will cut a thread in the work which is only 75 percent as deep as the thread on the tap. The other 25 percent of the depth of thread on the tap provides clearance between the tap hole and the root diameter of the tap. (See fig. 2-6-28.) This makes tapping easier.

If the tap drill selected is oversize, the tap hole will be oversize, and the tap can cut only shallow threads in the work. (See fig. 2-6-29.)

Figure 2-6-28.—Proper size drilled hole for tapping.

Figure 2-6-29.—Oversize drilled hole for tapping.

Figure 2-6-30.—Undersize drilled hole for tapping.

With less than a full 75 percent depth of thread, stud or capscrew threads usually strip.

If the tap drill selected is undersize, the tap hole will be undersize, being perhaps equal to the

9268

root diameter of the tap as shown in figure 2-6-30. Then there will be no clearance, and the tap will turn hard, tear the threads, and probably break.

CUTTING MACHINE THREADS WITH TAPS

A 50-50 mixture of white lead and lard oil, applied with a small brush, is highly recommended as a lubricant when tapping in steel. When using this lubricant, tighten the tap in the tap wrench and apply the lubricant to the tap. Start the tap carefully with its axis on the center line of the hole. The tap must be square with the surface of the work, as shown in figure 2-6-31.

Figure 2-6-31.—Using a square to ascertain a tap is square with the work.

To continue tapping, turn the tap forward two quarter turns, back it up a quarter turn to break the chips, and then turn forward again to take up the slack. Continue this sequence until the required threads are cut. Lard oil alone is sometimes used for lubrication, and is conveniently applied from an oil can. After you cut for the first 2 or 3 full turns, you no longer have to exert downward pressure on the wrench. You can tell by the feel that the tap is cutting as you turn it. Don't permit chips to clog the flutes or they will prevent the tap from turning. When the tap won't turn and you notice a springy feeling, stop trying immediately. Back the tap up a quarter turn to break the chips, clean them out of the flutes with a wire as shown in figure 2-6-32,

Figure 2-6-32.—Using a wire to clear chips from flute of a tap.

add some more lubricant, and continue tapping. When the tap has cut threads through the hole, the tap will turn with no resistance.

To tap a blind hole, start with the taper tap. For a blind hole you will need all three types—the taper, plug, and bottoming taps. Be sure they are the size and thread series you need, and that the tap hole is the size called for by the working drawing and the chart in appendix II.

Begin with the taper tap. Handle it as described and shown before. Figure 2-6-33A shows the taper tap just starting to cut. In figure 2-6-33B it has cut a little farther. In figure 2-6-33C it has bottomed in the hole after having cut several full threads near the top of the hole. This completes the work to be done with the taper tap.

Figure 2-6-33.—Tapping a blind hole with a taper tap.

9269

Figure 2-6-34.—Tapping a blind hole with a plug tap.

In figure 2-6-34A the plug tap has entered the few full threads cut by the taper tap. At figure 2-6-34B it has continued these threads a little farther down into the hole. At figure 2-6-34C it has bottomed in the hole. This is all the work that you can do with the plug tap. It has cut full threads about halfway down the tap hole before bottoming.

Figure 2-6-35.—Finish tapping a blind hole with a bottoming tap.

In figure 2-6-35 the bottoming tap has been substituted for the plug tap. In figure 2-6-35A it has been run down the full threads cut by the plug tap and is ready to cut more full threads. In figure 2-6-35B it has cut a few more threads, and in figure 2-6-35C it has bottomed in the hole. The blind hole has now been completely tapped.

Because these threads are being tapped in a blind hole, chip removal must be done differently. To remove chips, back the tap completely out of the hole very frequently, invert the stock, if possible, and jar out the chips or work them out of the hole with a wire while the stock is in the inverted position. If the work cannot be inverted, blow out the chips with air. Chip removal in tapping blind holes is much more difficult to do and is very important because chips will fall ahead of the tap through the flutes and accumulate in the bottom of the blind hole. Until these chips are removed, none of the three taps can complete its work. In tapping blind holes alternate with tapping and chip removal until each of the three taps bottom in the blind hole.

When you have finished using the three taps, brush the chips out of their teeth, oil them well with lubricating oil, wipe off the surplus oil, and replace them in the threading set.

CUTTING MACHINE THREADS WITH DIES

To cut threads on a piece of round stock—1/2—13 N.C. on a 1/2-inch rod in this case—first grind a chamfer on the end of the rod as shown in the working drawing in figure 2-6-27. Then hold the rod vertically in the vise to cut the threads. The working drawing in figure 2-6-27 calls for a 1/2-13N.C.-1 thread. The figure 1 after the N.C. indicates that a class 1 fit is required. A class 1 fit is a loose fit. The fit is controlled while threading the round stock. We tap the threads in the hole first as there is no way to adjust a tap. However, as threading dies are usually adjustable, we can control the fit of the threaded rod in the tapped hole by adjusting the threading die.

The adjustable round split die shown in figure 2-6-36 has an adjusting screw at A. By

Figure 2-6-36.—Assembling an adjustable round split die to diestock.

9270 case

tightening this screw and spreading the die slightly, it will cut less deeply into the rod and the fit in the tapped hole will be tighter. The shallow hole at B is placed in the die stock opposite the adjustable handle E and serves as a drive hole. Also, when the adjustable handle is tightened, it holds the split die together and against the adjusting screw to maintain the setting while the die is cutting. The threads or cutting teeth of the die are chamfered or relieved at C to help start the die squarely on the round stock. The die is put into the die stock with the face with the unchamfered teeth against the shoulder, D.

Figure 2-6-37.—Assembling a plain round split die to diestock.

Figure 2-6-37 is a plain round split die and die stock. At A, where the die is split, there is no adjusting screw. There are shallow holes at B and C, on both sides of the split, opposite which there are setscrews in the die stock at D and E. F is the adjusting screw which is pointed and enters the split A in the die. D and E are the holding setscrews. They have flat points and are tightened after the setting is made with F. D and E hold the adjustment and furnish the drive as they enter the shallow holes B and C shown in figure 2-6-37.

Figure 2-6-38 shows a section of the die in the die stock and its relation to the chamfer on the end of the work. The taper on the face of the die will accept the chamfer on the end of the work to start the threads square with the common center line.

To thread the work, brush some 50-50 white lead and lard oil on the rod. Start the die square with the work. Hold one handle with each hand, apply downward pressure, and turn clockwise until you feel the thread has been started. When the die has started to cut, rotate the die stock

Figure 2-6-38.—Position of diestock in relation to chamfer on end of work.

two quarter turns, back it off one quarter turn to break the chips, and repeat the cutting (see fig. 2-6-39). When you have cut enough threads so that the rod comes through the back of the die, remove the die and try the rod in the tapped hole.

Figure 2-6-39.—Cutting outside threads on round stock.

Adjusting a threading die to produce a thread of the proper fit is a trial-and-error procedure. This was a trial run. If the fit is too loose, cut off and discard the portion of the rod that you threaded. Then expand the die by tightening the pointed setscrews (or the adjusting screw) so that the die will cut shallower threads on the rod and produce a tighter fit.

9271

If the fit is too tight, it will not be necessary to discard the threaded portion of the rod. Contract the die by backing off (loosening) the pointed setscrew (or the adjusting screw) to decrease the size of the split in the die. This will cause the die to remove more metal, when cutting, and produce a looser fit. Then run the die down the cut threads that were too tight. Now test the fit again by turning the threaded end into the tapped hole.

When you have finished the threading job, remove the die from the die stock, carefully clean out all the loose chips, and apply plenty of oil. Wipe off the surplus oil and put the die and die stock away in the threading set where they will be protected and ready for the next job.

RECONDITIONING MACHINE THREADS

To recondition machine threads, when the damage is not serious, the general practice is to select the proper threading die, one type of which is shown in figure 2-6-40A. Put it in a die stock, and run over the threads that are damaged. For steel, lubricate with a 50-50 mixture of white lead and lard oil, lard oil alone, or lubricating oil if the others are not available. Use no lubricant for brass and copper. Start the die with the chamfered face of the die which is shown in the figure.

A B

44.151

Figure 2-6-40.—Two thread reconditioning tools.

The screw and bolt rethreading die, shown in figure 2-6-40B, is designed especially for reconditioning threads. The six sets of cutting teeth, in place of the customary four sets on a threading die, provide better alignment while the die is recutting damaged threads. Turn this rethreading die with any type of wrench or hold the die in a vise and turn the threaded piece through it.

Figure 2-6-41.—Thread restorer.

When only the first thread or the first 2 or 3 threads are damaged, and a perfect thread is not absolutely necessary, a three-square file can be used to touch up the tops of the damaged threads. A knife file will get down a little deeper into the threads when necessary.

The thread restorer shown in figure 2-6-41 resembles a square file. Each face is designed to match a certain pitch-screw thread. Two sizes of this tool are available, each one covering eight different machine-thread pitches. Together they cover a range of from 9 threads per inch through 32 threads per inch. Use this thread restorer as you would a file, maintaining the proper angle (that of the threads) as you go over the damaged threads.

Tools of this type are available for external pipe threads as well as for machine threads. The thread restorer for internal pipe threads, however, is similar to a tap. This type of thread restorer, whether internal or external, removes metal. Therefore, the thread that remains as a restored thread will not be a perfect or full thread. Where the crest of the original thread was battered over, the crest of the restored thread will be noticeably flat. Threads restored in this manner are, for practical purposes, as strong as new threads. They will again enter a nut or tapped hole.

Another type of thread restorer is shown in the 2" to 4" size in figure 2-6-42. This tool is not designed to cut new threads, but only as a maintenance and repair tool. Its action is a reforming action and not a cutting action. Therefore no metal is removed from the thread that is being forced back to its original shape. Only four sizes of this tool are necessary to cover thread diameters from one-quarter inch to 6 inches. A fifth size takes all diameters from 6 to 12 inches, inclusive. Each size will fit any pitch, left- or right-hand threads, standard pipe or machine thread, within the size limits specified, and no change of blades or dies is necessary. This restorer will not work on Acme threads.

To operate this thread restorer, simply slip it over the threads with the arrow on top, or toward you. Then tighten the jaws or blades

Figure 2-6-42.—Adjustable type thread restorer.

44.153

to a snug fit into the threads close to the back of the thread where no damage has been done. Then, just as you would remove a nut, turn the tool counterclockwise in the direction of the arrow on right-hand threads. To restore left-hand threads, first flop the tool over so that the face of the tool having the arrow is away from you. Then, after bringing the jaws up snug, run the tool off of the left-hand threads by turning it clockwise so that it will move toward you. Notice that this type of thread restorer normally works from the bottom or back of the thread out toward the end, restoring the threads as it progresses.

In most cases, restorers slide easily over key ways and milled flats on threaded parts. It may be found that the milled flat is rather wide on large-diameter jobs. In such cases threads can still be restored and the tool will negotiate the flat if you will clamp a half round piece of soft wood on the flat and operate the tool as directed. When this is necessary, it is usually on work of 2-inch diameter or larger. When used on studs or bolts having cotter pin holes, a small wooden plug in the hole will avoid breaking teeth. Keep the restorer clean and well oiled both in use and in storage.

CUTTING INTERNAL PIPE THREADS

Pipe threads are tapered threads to provide an airtight and liquidtight joint. A 3/8" machine thread tap and a 3/8" pipe thread tap are compared in figure 2-6-43 to show their differences. The 3/8" machine thread tap will cut machine threads in a hole so that a 3/8" cap screw, having the same thread, can be screwed into the hole. The 3/8" pipe thread tap will cut pipe threads in a hole so that a 3/8" threaded pipe can be screwed into the hole. Because pipe diameters are measured and given as inside diameters, and the wall thickness of the pipe must be taken into consideration, the 3/8" pipe thread tap in figure 2-6-43 is noticeably larger than the 3/8" machine thread tap. It should also be noted that the pipe thread tap is tapered, but the machine thread tap is not.

The N. P. T., which formerly stood for National Pipe Thread, is still used as a carryover and now refers to the new name for the same thread, American Standard Taper Pipe Thread. This standard taper is 3/4" per foot.

To select the proper tap drill for the pipe tap that you will use to tap a hole to take a

Figure 2-6-43.—Comparison of machine thread tap and pipe thread tap.

given size of threaded pipe, refer to figure 2-6-44. For example, if you want to drill and tap a hole to take a 3/8" pipe thread, find the 3/8" pipe tap in the Pipe Tap Size column. Opposite this, in the Tap Drill Size column, is 19/32", the proper tap drill to use for a 3/8" pipe tap.

Pipe Tap Size	Tap Drill Size	Pipe Tap Size	Tap Drill Size
1/8	11/32	2	2 3/16
1/4	7/16	2 1/2	2 5/8
3/8	19/32	3	3 1/4
1/2	23/32	3 1/2	3 3/4
3/4	15/16	4	4 1/4
1	1 5/32	4 1/2	4 3/4
1 1/4	1 1/2	5	5 5/16
1 1/2	1 23/32	6	6 3/8

Figure 2-6-44.—American Standard pipe tap drill sizes.

To cut internal pipe threads, drill a tap hole in the stock to be tapped and, following the suggested procedure for tapping machine threads given elsewhere in this book under the heading Cutting Machine Threads With Taps, run the pipe tap into the tap hole. Notice that the first few threads on the pipe tap are ground away. This makes starting easier. Plenty of lard oil is the standard lubricant for steel. Tap copper and brass with no lubricant. The depth to which it is desirable to tap pipe threads is usually determined by turning the threaded pipe into the tapped hole for a trial. As shown in figure 2-6-45, the last few threads on the pipe should still be visible when the pipe is drawn up tight in the tapped hole. Reference to the table in figure 2-6-46 shows the values of dimension A for various sizes of pipe up to 12".

Size of Pipe, Inches	Dimension A, Inches	Size of Pipe, Inches	Dimension A, Inches	Size of Pipe, Inches	Dimension A, Inches
1/8	1/4	1 1/2	11/16	5	1 1/4
1/4	3/8	2	3/4	6	1 5/16
3/8	3/8	2 1/2	15/16	7	1 3/8
1/2	1/2	3	1	8	1 7/16
3/4	9/16	3 1/2	1 1/16	9	1 1/2
1	11/16	4	1 1/8	10	1 5/8
1 1/4	11/16	4 1/2	1 3/16	12	1 3/4

44.156

Figure 2-6-45.—Length of thread on pipe required to make a tight joint.

Nominal Size	Outside Diameter	Nominal Size	Outside Diameter
1/8	13/32	3 1/2	4
1/4	17/32	4	4 1/2
3/8	11/16	4 1/2	5
1/2	27/32	5	5 9/16
3/4	1 1/16	6	6 5/8
1	1 5/16	7	7 5/8
1 1/4	1 21/32	8	8 5/8
1 1/2	1 29/32	9	9 5/8
2	2 3/8	10	10 3/4
2 1/2	2 7/8	11	11 3/4
3	3 1/2	12	12 3/4

44.157

Figure 2-6-46.—Approximate O.D. of standard wrought iron pipe.

The general practice in tapping holes for pipe threads is to drill the proper size tap hole and then start the pipe tap right into the tap hole. Some men recommend using a pipe reamer, especially when large deep holes are to be

9274

tapped. A pipe reamer has the same 3/4" per foot taper as a pipe tap. A reamed pipe tap hole would have the same shape as the pipe tap, and therefore would make tapping easier and reduce wear on the tap.

CUTTING EXTERNAL PIPE THREADS

Usually, both ends of a pipe are threaded with external pipe threads. Notice, in all the figures showing pipe threads, that they are V-shaped. The standard 3/4" taper per foot of pipe threads is equal to 1/16" per inch. Therefore, the taper of the threads on each side of the pipe is 1/32" taper per inch. This taper cannot be changed. This produces a tight joint. The angle between sides of the threads is 60°, and several threads on the end of the pipe are perfect threads. The next few have V-bottoms but flat tops, and the last few threads have both flat tops and bottoms. Each size of pipe has a certain number of threads per inch, built into the pipe taps and dies.

Adjustable pipe dies have a reference mark on each die which, when lined up with the corresponding reference mark on the die stock, will give a standard-size thread. You adjust the dies one way or the other from the reference mark to cut a thread with the fit you want.

To cut external threads on iron pipe, first determine its nominal size. Nominal size means the "name size" of the pipe such as 1/8", 3/4", and so on. Except in the sizes below 1", nominal sizes correspond closely to inside diameters. For 1" pipe and larger, measure the I.D. with your rule, to the closest 1/32", and you will have nominal size. For sizes below 1", you can determine nominal size by measuring the O.D. to the nearest 1/32" and reading the corresponding nominal size on the chart in figure 2-6-46. This method can also be employed for sizes 1" and above in lieu of the I.D. measurement.

To begin cutting, put the die stock on the pipe so that the pipe passes through the guide and enters the tapered face of the pipe die. Turn the die stock clockwise for right-hand threads, applying pressure only when starting. It is not necessary to turn the die back and forth as you do when cutting machine threads. Pipe-threading dies can cut continuously because they cut only as many threads on the pipe as there are on the die itself and because there is plenty of room in a pipe die for the chips to escape. After the die has taken hold, it will feed itself. When cutting threads on steel pipe, apply lard oil to the pipe and die where the cutting is actually taking place. Continue turning until the end of the pipe has gone through the die and is flush with the near face. See figure 2-6-47.

11.3.4

Figure 2-6-47.—Threading an external pipe thread with a pipe die.

This will give you the length of thread called for in the table in figure 2-6-45. Notice that, in the assembled pipe joint in figure 2-6-45, several threads remain on both pipe and fitting to permit further tightening should a leak develop. Dimension A in figure 2-6-45 is the length of thread on pipe required to make a tight joint.

REAMING OPERATIONS

Reaming operations are jobs that smoothly enlarge drilled holes to an exact size and finish the hole at the same time. A hole that has been made by drilling is usually slightly oversize. This is quite satisfactory for holes in which bolts or rivets are placed. When greater accuracy and a smooth finish are required, the hole is first drilled undersize and then finished by reaming. Reamers are also used to remove burrs from the inside diameters of pipe and drilled holes.

Most reaming operations are done by hand-turning the reamer; however, some reamers are designed for operation on power machines. Never use a reamer that is designed for hand-reaming on a power machine as the handreamers cannot withstand the higher speeds.

REAMING A HOLE WITH A SOLID STRAIGHT REAMER

A solid straight-hole reamer is used for most work, since it is the most accurate and rugged

44.158

Figure 2-6-48.—Using a tap wrench to turn a hand reamer.

of the straight-hole reamers. The straight-hole handreamer is turned by means of a tap wrench that is tightened on the square end of the reamer shank. (See fig. 2-6-48.) Secure the work in a vise so that the hole to be reamed is perpendicular to the top of the vise jaws. Position the reamer at the top of the hole (fig. 2-6-49). Straight-hole reamers have a slight taper at the end so that they will fit into the hole easily. Turn the wrench clockwise very slowly until the reamer is centered in the hole.

44.159

Figure 2-6-49.—Reaming a hole with a straight hole reamer.

After the reamer is centered in the hole, turn the wrench clockwise with a steady firm pressure until the reamer has been turned all the way through the hole. When reaming steel, use cutting oil or machine oil to lubricate the tool. When reaming soft iron, do not lubricate the tool. To remove the reamer from the hole turn the wrench clockwise and raise the reamer simultaneously.

NOTE: Turning the wrench too fast or too slowly will cause the reamer to chatter, producing an unevenly reamed hole.

INSTALLING A TAPER PIN

To install a tapered pin, refer to the blueprint or drawing for the proper size of pin to use. The size will be given as a number and length in inches (see the table in figure 2-6-50.) For instance, a No. 3 pin 1 3/4" long might be specified. Then, when you have the proper pin, measure the diameter of its small end and drill a hole of that size through for example, the hub of a flange and a shaft while the flange is in place on the shaft. (See fig. 2-6-51.) Then select the same number of tapered pin reamer, a No. 3 in this case.

No. of Pin	Diameter at Large End		Max. Length
	D	D	L
00000	0.094	3/32	3/4
0000	.109	7/64	7/8
000	.125	1/8	1
00	.141	9/64	1 1/8
0	.156	5/32	1 1/4
1	.172	11/64	1 1/2
2	.193	3/16	1 3/4
3	.219	7/32	1 3/4
4	.250	1/4	2
5	.289	19/64	2 1/4
6	.341	11/32	3
7	.409	13/32	3 3/4
8	.492	1/2	4 1/2
9	.591	19/32	5 1/4

44.160

Figure 2-6-50.—Chart for Standard taper pins.

Figure 2-6-52 shows specifications of various sizes of reamers. The specifications given opposite the reamer numbers in the left-hand column of the table in figure 2-6-52 are the dimensions of the reamers. The small end of the reamer should just enter the hole you drill and, if the proper size of reamer has been selected, the pin will fit exactly. Turn the tapered pin reamer with a tap wrench

slowly and in a clockwise direction only, lifting it out of the hole to clean away the chips while it is still turning. If you reverse the direction of the reamer, chips may be wedged behind its cutting edges, causing them to break. Ream brass dry but apply cutting oil liberally when reaming steel. Try the taper pin in the hole several times as the reaming progresses. Stop reaming when the pin protrudes the same amount on both sides of the hub of the gear.

REMOVING BURRS WITH A PIPE REAMER

After a piece of pipe has been cut, the ends should be reamed to remove the burr that is left on the inside of the pipe. This burr, if not removed, will restrict the flow of fluid in the pipe. Besides the reamer to trim the burr inside the pipe you will need a vise to hold the pipe steady. After making sure the pipe is held firmly in the vise, insert the reamer in the end of the pipe and turn the handle. (See fig. 2-6-53.) Rotate the handle of the reamer

11.3.4A

Figure 2-6-53.—Using a pipe reamer to remove burrs from pipe.

clockwise in short even strokes until the burrs inside the cut piece of pipe are completely removed. Remove the reamer from the pipe by rotating it clockwise.

CUTTING PIPE AND TUBING

In nearly all ratings in the Navy, it will be necessary to cut pipe and/or tubing from time to time. The tools for doing this are generally kept in a tool room instead of in an individual mechanic's tool kit.

Pipe cutters are used to cut pipe made of steel, brass, copper, wrought iron, and lead. Tube cutters are used to cut tubing made of

9277

iron, steel, brass, copper, and aluminum. The essential difference is that tubing has considerably thinner walls than piping. A cold chisel and hammer are used to cut pipe that is made from cast iron. If a pipe or tubing cutter is not available, a hacksaw may be used to cut either pipe or tubing.

CUTTING IRON PIPE TO LENGTH WITH A PIPE CUTTER

Before you cut pipe, make certain the required correct length is determined. There are three methods of measuring threaded pipe, and you must understand these methods if the pipe is to be cut to the correct length. (See fig. 2-6-54.)

Figure 2-6-54.—Proper methods for measuring pipe to desired lengths.

The end-to-end method includes measuring the threaded portions of the pipe and measuring the pipe from end to end. The end-to-center method is used on a section of pipe that has a fitting screwed on one end only; measure from the free end of the pipe to the center of the fitting at the other end of the pipe. The center-to-center method is used when both ends of the pipe have fittings; measure from the center of one fitting to the center of the other fitting at the opposite end of the pipe.

The approximate length of thread on 1/2- and 3/4-inch wrought iron or steel pipe is 3/4 inch. On 1-, 1 1/4-, and 1 1/2-inch pipe, it is approximately 1 inch long. On 2- and 2 1/2-inch pipe, the length of thread is 1 1/8 and 1 1/2 inches respectively.

To determine the length of pipe required, take the measurement of installation such as center to center of the pipe requiring two fittings. Measure the size of the fittings as shown in figure 2-6-54. Subtract the total size of the two fittings from the installation measurement. Multiply the approximate thread length by 2 and add the result to the length obtained. This will give the length of pipe required.

After the length of the pipe has been determined, measure the pipe and mark the spot where the cut is to be made with a scriber or crayon. Lock the pipe securely in a pipe vise.

Inspect the cutter to make sure that there are no nicks or burrs in the cutting wheel. Open the jaws of the cutter by turning the handle counterclockwise. Position the cutter around the pipe at the marked point. Make sure the cutting wheel is exactly on the mark and close the jaws of the cutter lightly against the pipe by turning the cutter handle clockwise. After making contact, turn the cutter handle clockwise one-fourth of a turn more. This will put a bite on the pipe.

Grasp the cutter handle and rotate the cutter as a whole one complete revolution, swinging it around the pipe in the direction indicated in figure 2-6-55. Turn the cutter handle clockwise

Figure 2-6-55.—Cutting pipe with a pipe cutter.

9278

one-fourth of a turn more to take another bite on the pipe and rotate the cutter another complete revolution. Keep the cutter perpendicular to the pipe at all times or the wheel will not track properly. Repeat this operation until the pipe is cut. Remove the small shoulder on the outside of the pipe with a file and remove the burr on the inside with a reamer.

CUTTING METALLIC TUBING WITH A TUBE CUTTER

Copper tubing is one of the most generally used kinds of metallic tubing readily cut with a tube cutter. This cutter works the same as a pipe cutter but is smaller. To cut tubing, place the tube cutter with the cutting wheel on the mark where the cut is to be made. Move the cutting wheel into light contact with the tubing. See step 1 in figure 2-6-56. Then swing the handle around the tubing as you feed

Figure 2-6-56.—Steps in cutting tubing with a tube cutter.

the cutting wheel a little for each revolution by turning the screw adjustment. Different wall thicknesses, kinds, and diameters of metallic tubing require different feeds. Step 2, figure 2-6-56 indicates the direction of rotation. The feed pressure is correct when it keeps the wheel cutting but does not flatten the tubing.

Figure 2-6-57.—Cutting tubing close to the base of a flare.

The design of some tubing cutters will permit cutting off a flared end close to the base of the flare. In figure 2-6-57, notice the groove in the backup roller. Place the flare in this groove so that the cutting wheel rides at the base of the flare. Then cut off the flare as you would cut tubing.

Burrs that form may be similar to those formed when cutting pipe. Remove the inside burr with the reamer attached to the tubing cutter opposite the handle. See figure 2-6-58.

Figure 2-6-58.—Reaming the burrs from a piece of tubing.

In some cases a three-cornered scraper, pocketknife blade, or round file may work better than the reamer. After reaming clean out the chips. Then remove any outside burr with a mill file.

USING HACKSAWS

Hacksaws are among the most useful tools for cutting metal. They may be either hand-operated or powered by electricity. The power hacksaw is a great time-and-labor saver in a shop where much metalwork is done. It will cut much faster and more accurately than can usually be done by hand. When cutting heavy bars, the power hacksaw can be started and allowed to run by itself while other work is being done in the shop.

9279

The hand-operated hacksaw will be used by a greater number of people in the Navy; therefore, the use of the hand hacksaw will be discussed in this section.

Like the file, however, the hacksaw is often used improperly. Although it can be used with limited success by an inexperienced man, a little thought and study given to its proper use will result in faster and better work and less dulling and breaking of blades.

Good work with a hacksaw depends not only upon the proper use of the saw, but also upon the proper selection of the blades for the work to be done. Figure 2-6-59 will help you select the proper blade to use when sawing metal with a hacksaw. Coarse blades with fewer teeth

Figure 2-6-59.—Selecting the proper hacksaw blade.

per inch cut faster and are less liable to choke up with chips. However, finer blades with more teeth per inch are necessary when thin sections are being cut. The selection should be made so that, as each tooth starts its cut, the tooth ahead of it will still be cutting.

To make the cut, first install the blade in the hacksaw frame (fig. 2-6-60) so that the

Figure 2-6-60.—Installing a hacksaw blade.

teeth point away from the handle of the hacksaw. Hand hacksaws cut on the push stroke, whereas power hacksaws cut on the pull stroke. Tighten the wingnut so that the blade is definitely under tension. This helps make straight cuts.

Hold the job in a vise with a minimum of overhang. This will reduce vibration, give a better cut, and lengthen the life of the blade. Have the layout line outside of the vise jaw so that the line is visible while you work. The index finger of the right hand, pointed forward, aids in guiding the frame. (See fig. 2-6-61.)

Figure 2-6-61.—Proper way to hold a hacksaw.

A stroke is one forward-and-back movement of the hacksaw frame. Let your body sway ahead

and back with each stroke. Apply pressure on the forward stroke, which is the cutting stroke, but not on the return stroke. From 40 to 50 strokes per minute is the usual speed. Long, slow, steady strokes are much preferred.

44.169

Figure 2-6-62.—Making a long cut near the edge of stock.

For long cuts (fig. 2-6-62) rotate the blade in the frame so that the length of the cut is not limited by the depth of the frame. Hold the work with the layout line close to the vise jaws, raising the work in the vise as the sawing proceeds.

Saw thin metal as shown in figure 2-6-63. Notice the long angle at which the blade enters the saw kerf. This permits several teeth to be cutting at the same time.

44.170

Figure 2-6-63.—Cutting thin metal with a hacksaw.

Metal which is too thin to be held, as shown in figure 2-6-63, can be held between blocks of wood, as shown in figure 2-6-64. As shown in figure 2-6-64A, the wood provides support for several teeth as they are cutting. Without the wood, as shown at B in figure 2-6-64, teeth will be broken due to excessive vibration of the stock and because individual teeth have to absorb the full power of the stroke.

Cut thin metal with layout lines on the face by using a piece of wood behind it. (See fig.

44.171

Figure 2-6-64.—Cutting thin metal between two wooden blocks.

2-6-65.) Hold the wood and the metal in the jaws of the vise, using a C-clamp in addition when necessary. The wood block helps support the blade and produces a smoother cut. Using the wood only in back of the metal permits the layout lines to be seen.

44.172

Figure 2-6-65.—Cutting thin metal using wood block with layout lines.

To remove a frozen nut with a hacksaw, saw into the nut as shown in figure 2-6-66, starting the blade close to the threads on the bolt or stud and parallel to one face of the nut as shown in figure 2-6-66A. Saw parallel to the bolt until the teeth of the blade almost reach the lockwasher. Lockwashers are hard and will ruin hacksaw blades, so do not try to saw them. Figure 2-6-66B shows when to stop sawing. Then, with a cold chisel and hammer, remove this one side of the nut completely by opening the saw kerf. Put an adjustable wrench across this new flat and the one opposite, and again try to remove the frozen nut. As very little original metal remains on this one side of the nut, the nut will either give or break away entirely and permit its removal.

9281

Figure 2-6-66.—Removing a frozen nut with a hacksaw.

To saw a wide kerf in the head of a cap screw or machine bolt, fit the hand hacksaw frame with two blades side by side, and with teeth lined up in the same direction. With slow, steady strokes, saw the slot approximately one-third the thickness of the head of the cap screw as shown in figure 2-6-67. Such a slot will permit subsequent holding or turning with a screwdriver when it is impossible, due to close quarters, to use a wrench.

Most power hacksaws found in small shops will make a square cut in stock up to 4 by 4 inches and take a standard 12-in. power hacksaw blade. This size saw is generally operated by a 1/3 horsepower electric motor. Power hacksaws cut on the pull stroke and automatically release the pressure on the backstroke. The pressure applied on the cutting stroke is adjustable.

As with hand hacksaws the blades should be selected according to the kind of sawing to be done. Blades with 18 teeth per inch are recommended for cutting thin sections like angle iron, pipe, and tubing, and are generally quite satisfactory for general work in the shop. Coarser toothed blades with 14, or even 10 teeth per inch, may be used for faster cutting in heavy stock.

Some of the main points to remember when operating a power hacksaw are:

1. Always clamp the work securely in the saw vise.
2. Before starting the saw, be sure the blade is up and out of contact with the work. After the blade is in motion, let it down gently onto the work, holding up on the handle slightly to reduce the pressure while the blade is starting to cut.
3. Always keep the blade tight in the saw frame.
4. Use a suitable cutting pressure on the blade, just enough to keep it cutting well.
5. Clamp the work so that the blade will not have to cut straight across thin sections.
6. Be sure to insert the blades so that the teeth will point in the direction of cutting.
7. Clamp the angle irons with the ridge up. Two or more may be cut at the same time by nesting them.
8. Do not push down on the saw to add pressure to the blade. The teeth can cut only as fast as their size will permit.
9. Run the saw at the speed recommended by the manufacturer.

Figure 2-6-67.—Cutting a wide kerf in the head of a capscrew or bolt.

PART II

Section 7

MISCELLANEOUS SKILLS

A number of miscellaneous skills that are common throughout the Navy cannot be properly categorized in any of the foregoing sections. For example, skills introduced in this section may require the use of tools that are not used in such operations as cutting, grinding, measuring, etc. To accomplish some of these skills, a combination of particular materials, tools, and work methods is needed.

GLASSCUTTING

Two glasscutters are generally available for use in the Navy. One is the single wheel, general purpose type (fig. 2-7-1), while the other is a 2-to 24-inch circular capacity type incorporating a graduated beam (not illustrated).

A glasscutter actually does not cut glass; it splits it. If the wheel is sharp and it is drawn over the glass at the right speed and pressure, it makes a fine score or groove by slightly crushing or pulverizing the glass under the edge of the wheel. The beveled sides of the wheel act as wedges which push against the sides of the groove and pry the glass apart so that a crack is started. If a crack fails to start in the cutting, tap the scratch or score with the ball end of the glasscutter to start a crack.

Figure 2-7-1.—Using a glasscutter.

Before trying to make a finish cut in a piece of glass, get a scrap piece and make several cuts on it. This helps you discover the proper speed and pressure that are required to get a smooth edge.

Ordinary window glass comes in two thicknesses, single light and double light. Single light is thinner and easier to cut. Plate glass up to 1/4 inch in thickness can be cut in the same manner as ordinary window glass. Safety glass, which consists of two or more glass sheets cemented together by a transparent plastic, requires special cutting equipment.

MAKING STRAIGHT CUTS IN ORDINARY GLASS

To make straight cuts in glass, follow the steps shown in figure 2-7-1. In scoring the glass, hold the glasscutter as you would a pencil. Draw the glasscutter toward you over the surface of the glass.

To break a small piece of glass, grasp the piece in both hands with the score mark up. Then push upward with your fingers beneath the score mark, and downward with your thumbs. The glass will break almost instantaneously along the entire score mark.

Straight cuts can also be made with the use of a straightedge. The straightedge must be held firmly in place, however. Figure 2-7-2 shows a straightedge held in place with a pair of C clamps. Other means of holding the straightedge in place are also acceptable. In placing the straightedge, make allowance for the fact that the wheel of the glasscutter must pass through the centers of the locating marks. Therefore, the score mark when made will be a slight distance from the straightedge itself.

9283

Figure 2-7-2.—Using a straightedge when cutting glass.

Dip the end of the glasscutter in kerosene before drawing it across the surface of the glass. Apply only light or medium pressure for glass that is about 1/8-inch thick. Too much pressure will tend to chip the glass along both sides of the score mark. The score mark should be only one barely visible line on the surface of the glass extending the entire distance from edge to edge. Make it in one pass. To go over it a second time may cause an uneven break.

For breaking large sheets of glass by scoring, lay the glass as shown in figure 2-7-3A, with the score mark on the top surface. Then tap the bottom surface just under the score mark, using the handle of the glasscutter. This will "start" the break at that point although the start may not be visible.

Then lay a piece of chalk line, or similar cord, on the bench top to raise the glass slightly, and place the score mark right over it. (See fig. 2-7-3B.) (In all glass work, the score mark is kept on the top face of the work.) Carefully apply downward pressure at points B and C, figure 2-7-3B, on both sides of the score mark. The crack that you started by tapping beneath one end of the score mark from the bottom surface of the glass will then almost instantly follow the score mark across the width of the sheet leaving the two pieces of glass in the clear. When pressure at points B and C starts the crack on its way from A to D, but the crack does not reach D, then apply pressure progressively toward D, but always slightly behind the point to which the crack has run. For short breaks, a matchstick can be substituted for the cord.

Figure 2-7-3.—Cutting large sheets of glass.

Figure 2-7-4 shows a break that did not follow the score mark. When this happens, grasp the remaining piece with glass pliers right up to the score mark and carefully apply pressure downward away from the score mark. A glass pliers is a broad-nosed pliers. If you do not have glass pliers, use ordinary pliers. It may be necessary to "nibble" off whatever scrap glass remains if the first break fails to follow the entire width of the glass.

Figure 2-7-4.—Using pliers to aid in separating glass.

CUTTING GLASS TO A PATTERN

To cut glass to a pattern, first lay out a full size drawing on paper, making certain the outline is heavy and distinct. Place the drawing under the pane of glass to be cut. Cut circles, ovals, and curves by tracing them through the glass with the cutter wheel. For straight lines, use a guide such as a woodstrip or a yardstick.

CUTTING LAMINATED SAFETY GLASS

To cut laminated safety glass, make the score mark just as you would for ordinary glass and open or snap the cut on one side. Then turn the sheet of glass over on the bench top and make another score mark exactly opposite the first one, and open this score mark separately just as you would for unlaminated glass. Use a cord or matchstick to assist in breaking the glass if necessary.

9284

When both glass faces of the laminated safety glass have been scored and cut or snapped, secure the glass to the bench top as shown in figure 2-7-5. Then pull horizontally with glass pliers or common pliers, with pads of rubber to protect the surface of the glass from the jaws. When the cut is opened up in this way, cut the layer of plastic with a razor blade as shown. Pulling horizontally prevents chipping the edges of the glass on the bottom side which is what would happen if the top of the cut were opened up by bearing down on the pliers rather than pulling horizontally.

Figure 2-7-5.—Cutting laminated safety glass.

For satisfactory cutting, laminated safety glass must be at a temperature of between 75° and 110° F. However, to facilitate stretching the plastic so that it can be cut with a razor blade, it may be necessary to raise the temperature above this. After the glass has been scored and snapped, heat the plastic by immersing the whole sheet of glass in hot water (160° to 170° F) for a short period not to exceed a minute. Cut the plastic membrane clear through immediately upon removing the glass from the hot water. Then wipe the plate dry and stand it on its edge until it has cooled to almost room temperature. Do not attempt to hurry the cooling with a fan or other means.

CUTTING GLASS TUBING

One way to cut glass tubing, as shown in figure 2-7-6, is to score the surface with one forward stroke of a three-cornered file. The corner of a mill file will also work well in the absence of a three-cornered file. Make the score mark at right angles to the center line of

Figure 2-7-6.—Cutting glass tubing with a three-cornered file.

the tube so that the tube will snap squarely across. To snap the tube, place it on the bench top with a matchstick or toothpick directly beneath the score mark. Then, holding one end securely, press down on the other end and the snap will be immediate.

If possible, cut glass tubing with the gage glasscutter shown in figure 2-7-7. Set the stop collar to permit the cutting wheel to be inserted the required distance into the end of the tubing to make the cut where you want it. The backup shoe will ride on the outside surface of the tube exactly opposite the cutting wheel. If the glass is pyrex glass, it may be necessary to use a new, sharp cutting wheel for each gage glass that is to be cut, because pyrex glass is extremely hard. Apply pressure on the handles of the gage glasscutter with one hand and rotate the glass with the other. The score mark will be on the inside of the tube.

Figure 2-7-7.—Using a gage glasscutter for cutting glass tubing.

To break the glass tubing at the score mark, hold the glass in both hands with your thumbs at the mark. (See fig. 2-7-8.) Then pull against your thumb pressure and away from the score mark. On some glass tubing this method may be more satisfactory than using a matchstick.

To remove the sharp corners at the fresh cut, hold the glass at the edge of the bench as shown in figure 2-7-9, then, with a piece of

9285 8850

Figure 2-7-8.—Breaking glass tubing at the scored mark.

Figure 2-7-9.—Smoothing the cut edge of glass tubing.

emery cloth wrapped around a file, work your way around the entire circumference of the tube with forward strokes.

STRIPPING INSULATED WIRE

Insulation may be stripped from wire by using one of several tools. However, a pocketknife or side cutting pliers are generally used for this work.

When using a pocketknife for stripping insulation, hold the wire in one hand and the knife in the other. Use your thumb to roll the wire over the blade of the knife to cut the insulation almost to the wire itself. (See figure 2-7-10A.) Then pull off or "strip" the short piece of insulation from the end of the wire. Because any nick in the wire will eventually cause a break, it is important not to cut clear through the insulation. By not cutting completely through the insulation, the blade of the knife never comes into contact with the wire itself, thus preventing any possible injury to the surface of the wire. However, cutting nearly through the insulation weakens it sufficiently so that the insulation can be stripped from the wire. This method is not recommended for stranded wire.

Another way to perform this operation is, while holding the wire in one hand and the pocketknife in the other, hold the wire against the knife blade with your thumb and cut the insulation off with several strokes of the blade, working around the wire with each successive stroke. (See fig. 2-7-10B.) Notice that the blade is held almost flat against the insulation. This low angle prevents the blade from cutting into the wire itself. This method is not recommended for stranded wire.

Figure 2-7-10.—Stripping insulated wire with a pocket knife.

Insulated wire can be stripped with the side cutting pliers, as shown in figure 2-7-11, by nicking the insulation all around, being careful not to break through to the wire itself, and stripping the short length of insulation off the end of the wire. Notice that, in figure 2-7-11A, the man's index finger is wedged between the handles of the pliers close to the joint. This affords better control over the cutting edges so that there

9286

is less chance that the insulation will be broken completely through. When the nick has been made all around the wire, press your thumb against the side of the pliers to break the insulation at the nick and, without changing the grip of the pliers, strip it off the end. (See fig. 2-7-11B.) Care must be exercised to avoid cutting too far through the insulation and nicking the wire.

1.21.8A

Figure 2-7-11.—Stripping insulated wire with side cutting pliers.

Insulated solid wire can also be stripped as shown in figure 2-7-12. Starting at the end of the wire, grip and crush the insulation between the flat places on the inside of the handles close to the hinged joint. In figure 2-7-12A, the insulation has been crushed and the wire exposed. Then, as shown in figure 2-7-12B, grasp the insulation close to the end of the crushed portion and tear it off. Although this method leaves a rather ragged appearing end on the remaining insulation, there is no possibility of damaging the wire.

BENDING AND FLARING METALLIC TUBING

External spring-type benders, shown in figure 2-7-13A, come in sizes to bend 1/4",

1.21.8B

Figure 2-7-12.—Stripping insulated wire with side cutting pliers.

5/16", 3/8", 7/16", 1/2", and 5/8" outside-diameter soft copper, aluminum, and other soft metallic tubing. To bend tubing with this type of bender, first select the size that will just slip over the size of tubing you want to bend. Then slip it over the tubing so that it centers at the middle of the proposed bend. Grasp the bender with both hands and make the bend. (See fig. 2-7-13B.) The restraining action of the bender will prevent the tubing from collapsing at the bend and will produce a smooth curve. To remove the bender, grasp the belled end and pull it off the tubing.

Internal spring-type benders, shown in figure 2-7-13C, come in sizes to bend 3/8", 1/2", and 5/8" outside diameter tubing. This type can be used when both ends of a length of tubing are flared and the external type cannot be applied. To bend tubing with an internal spring-type bender, select the proper size bender and slip it inside of the tubing. Insert it so that the center of its length is at the center of the proposed bend. Grasp the tubing with both hands and make the bend. If the bender sticks out of the end of the

9287

Figure 2-7-13.—Bending tubing with spring type tube benders.

tubing, remove it by pulling it out. If not, remove it with a fish wire or other simple means.

The bender shown in figure 2-7-14 is an open-side mandrel type. By open-side is meant that one side is open so that the bender can be placed on the tubing at any point along the length of the tubing. The mandrel is the circular portion of the bender around which the tubing is formed or bent. This type of bender is furnished in 3/16", 1/4", 5/16-, 3/8", and 1/2" sizes. Place the bender on the tubing at the point where the bend is required. Figure 2-7-14A, shows the zero line on the bender which indicates the start of the bend. Then close the bender, as shown in figure 2-7-14B, and by bringing your two hands toward each other, bend the tubing around the mandrel until the index line on the arm indicates the angle of the bend you require. Then open the bender, as shown in figure 2-7-14A and remove it from the tubing. For larger sizes of tubing similar mandrel-type benders are used. These are geared for greater mechanical advantage but their operation is basically the same.

Figure 2-7-14.—Bending tubing with an open-side mandrel type bender.

Tube flaring is a method of forming the end of a copper tube into a funnel shape so that it can be held by a threaded fitting. A partially threaded flare nut is slipped over the tube, the end of the tube is flared, the flare is seated with the inside of the flare against the end of a fitting which has threads on the outside, and then the flare nut is screwed onto the fitting, pushing the outside of the flare against the seating surface of the fitting.

The tube-flaring tool shown in figure 2-7-15 is one type which is commonly used to flare copper tubing. To flare the end of tubing, first check to see that it has been cut off squarely and has the burrs removed from both inside and outside. Remember to slip the flare nut on the tube before you make the flare. Then, as shown in figure 2-7-15A, open the flaring tool at the die which corresponds to the size of the tubing

Figure 2-7-15.—Flaring metallic tubing.

being flared. Insert the end of the tubing to protrude slightly above the top face of the die blocks. The amount by which the tubing extends above the blocks determines the finished diameter of the flare. The flare must be large enough so that it will seat properly against the fitting, but small enough so that the threads of the flare nut will slide over it. You determine the correct size by trial-and-error. Then as shown in figure 2-7-15B, close the die block and secure the tool with the wing nut. Use the handle of the yoke to tighten the wing nut. Then place the yoke over the end of the tubing (fig. 2-7-15C), and tighten the handle to force the cone into the end of the tubing. The completed flare should be slightly visible above the face of the die blocks.

REMOVING BROKEN BOLTS AND STUDS

When the removal of a broken bolt or stud from work is required, use plenty of oil to flood the part being worked on. Penetrating oil is the most effective. Time permitting, soak the area for several hours or overnight. A week's soaking may loosen a bolt which would otherwise have to be drilled out.

If enough of the broken piece protrudes from the job, take hold of it with locking pliers, as shown in figure 2-7-16, and carefully try to ease it out. The smaller sizes of bolts are very liable to twist off. If the bolt cannot be turned, further soaking with penetrating oil may help. Or try removing the pliers and jarring the bolt with light hammer blows on the top and around the sides. This may loosen the threads so that the bolt can then be removed with the locking pliers.

1.21C

Figure 2-7-16.—Removing a broken stud with locking pliers.

If a bolt has been broken off flush with the surface of the job, as shown in figure 2-7-17, it is sometimes possible to back it out of the hole with light blows of a prick punch or center punch.

44.188

Figure 2-7-17.—Removing a broken bolt with a prick punch.

However, if the bolt was broken due to rusting, this method will not remove it. If it cannot be removed by careful punching first on one side and then the other, a screw and bolt extractor may remove it. (See fig. 2-7-18B.)

When using this extractor, file the broken portion of the bolt to provide a smooth surface at the center for a punch mark, if possible. Then carefully center punch the exact center of the bolt (See fig. 2-7-18A.)

44.20BB

Figure 2-7-18.—Screw and bolt extractors for removing broken studs.

Refer to figure 2-7-19 to select the proper drill size to use according to the size of the broken bolt that you are trying to remove. If possible, drill through the entire length of the broken bolt. Then carefully work some penetrating oil through this hole so that it fills the cavity beneath the bolt and has a chance to work its way upwards from the bottom of the bolt.

9289

Extractor		Used For—		Use Drill Size Dia., Inches
Size No.	Overall Length, Inches	Nominal Screw And Bolt Size, Inches	Nominal Pipe Size, Inches	
1	2	3/16 - 1/4	--------	5/64
2	2 3/8	1/4 - 5/16	--------	7/64
3	2 11/16	5/16 - 7/16	--------	5/32
4	3	7/16 - 9/16	--------	1/4

12	6 1/4	3 - 3 1/2	2	1 15/16

Figure 2-7-19.—Chart for screw and bolt extractor.

The more time you let the penetrating oil work from both ends of the broken bolt, the better are your chances of removing it.

When drilling a hole in a stud which has broken off below the surface of the piece which it was holding, as shown in figure 2-7-20A, a drill guide will center the drill and may be preferred rather than a center punch mark.

When the hole has been drilled, and additional penetrating oil has had time to soak, put the spiral end of the screw and bolt extractor into the hole. Set it firmly with a few light hammer blows and secure the tap wrench as shown at B in figure 2-7-20. Carefully try to back the broken bolt out of the hole. Turn the extractor counterclockwise. This type of extractor is designed for right hand threads only.

A screw and bolt extractor can sometimes be used to remove a socket-head capscrew, also called an Allen head capscrew, when the socket has been stripped by the Allen wrench. (See fig. 2-7-21.) When attempting this removal, carefully grind off the end of the extractor so that it will not bottom before the spiral has had a chance to take hold. Figure 2-7-21B shows this end clearance. In doing this grinding operation,

Figure 2-7-20.—Removing a stud broken off below the surface.

Figure 2-7-21.—Removing an Allen head capscrew with a bolt extractor.

great care must be taken to keep the temperature of the extractor low enough so that the tip can be handled with the bare hands. If the hardness is drawn from the tip of the extractor by overheating during the grinding, the extractor will not take hold.

REMOVING A BROKEN BOLT AND RETAPPING HOLE

To remove a broken bolt and retap the hole, file the bolt smooth, if necessary, and center-punch it for drilling.

Then select a twist drill which is a little less than the tap-drill size for the particular bolt that has been broken. As shown in figure 2-7-22, this drill will just about but not quite touch the crests of the threads in the threaded hole or the roots of the threads on the threaded bolt. Carefully start drilling at the center punch mark, crowding the drill one way or the other as necessary so that the hole will be drilled in the exact center of the bolt. The drill in figure 2-7-22 has almost drilled the remaining part of the bolt away and will eventually break through the bottom of the bolt. When this happens, all that will remain of the bolt will be a threaded shell. With a prick punch or other suitable tool, chip out and remove the first 2 or 3 threads, if possible, at the top of the shell. Then carefully start a tapered tap into these several clean threads and continue tapping until the shell has been cut away and the original threads restored.

In cases where the identical size of capscrew or bolt is not necessary as a replacement, center-punch and drill out the old bolt with a drill larger than the broken bolt, as shown in figure 2-7-23A. Tap the hole first, and then finish it with a bottoming tap as shown in figure 2-7-23B. Replace with a larger size capscrew or stud.

Figure 2-7-22.—Removing a broken bolt and retapping hole to same size.

Figure 2-7-23.—Removing broken bolt and retapping hole to larger size.

REMOVING A BROKEN TAP FROM A HOLE

To remove a broken tap from a hole, generously apply penetrating oil to the tap, working it down through the four flutes into the hole. Then, if possible, grasp the tap across the flats with locking-type pliers. This operation is shown in figure 2-7-24. Carefully ease the tap out of the hole, adding penetrating oil as necessary.

Figure 2-7-24.—Removing a broken tap with locking pliers.

If the tap has broken off at the surface of the work, or slightly below the surface of the work, the tap extractor shown in figure 2-7-25 may remove it. Again, apply a liberal amount of penetrating oil to the broken tap. Place the tap extractor over the broken tap and lower the upper collar to insert the four sliding prongs down into the four flutes of the tap. Then slide the bottom collar down to the surface of the work

9291

9292

Figure 2-7-25.—Removing a broken tap with a tap extractor.

so that it will hold the prongs tightly against the body of the extractor. Tighten the tap wrench on the square shank of the extractor and carefully work the extractor back and forth to loosen the tap. It may be necessary to remove the extractor and strike a few sharp blows with a small hammer and pin punch to jar the tap loose. Then reinsert the tap remover and carefully try to back the tap out of the hole.

Each size of tap will require its own size of tap extractor. Tap extractors come in the following sizes: 1/4", 5/16", 3/8", 7/16", 1/2", 9/16", 5/8", 3/4", 7/8", and 1".

When a tap extractor will not remove a broken tap, it is often possible to do so by placing a hex nut over the tap (fig. 2-7-26), and plug welding the nut to the tap with an arc welder. Notice that the hole in the nut must be somewhat smaller than the tap to reduce the possibility of welding the nut and the tap to the job itself. Allow the weld to cool before trying to remove the tap. When the nut, tap, and job have come to room temperature, it is often helpful to heat quickly the immediate area around the hole with an oxyacetylene torch. This quick heating expands the adjacent metal of the work after which the removal of the tap may be less difficult. If

Figure 2-7-26.—Using a plug weld to remove a broken tap.

the heating is too slow, the tap will expand with the adjacent metal of the work and there will be no loosening effect.

SOLDERING

Soldering is used to join metallic surfaces such as copper, iron, nickel, lead, tin, zinc, and aluminum. It is particularly useful for securing electrical connections, joining sheet metal, and sealing seams against leakage. Soldered joints are not as strong as welded joints, and so are not used where any great mechanical strength is required. Electric soldering irons or guns are widely used for electrical connections, but soldering may also be done with coppers which do not have an electrical heating element.

Soldering requires relatively little equipment. For most soldering jobs, you will need only a source of heat, soldering coppers, solder and a flux. There are several different types of solder and solder fluxes used in the Navy. It is important that you understand which solder and flux to use when doing soldering jobs of any kind.

SOURCES OF HEAT

The sources of heat used for soldering with a copper vary according to the method used and the equipment that is available. Welding torches, blowtorches, forges, gas ovens, furnaces, and other heating devices may be used to heat soldering coppers which are used, in turn, to heat the metal being soldered and thus melt the solder. However, the heating devices are sometimes used for direct heating of the surfaces to be joined, in this case, the solder is melted by the heat from the heated surfaces.

New soldering coppers must be tinned (coated with solder) before they are used. If you overheat soldering coppers they must be retinned. After continued use, filing, and retinning, the tip of the copper tends to become too blunt or stubby. A copper in this condition is ineffective and requires forging to reshape its tip.

FORGING A SOLDERING COPPER

To forge a soldering copper, first hold the copper in a vise, gripping the copper itself and not the handle. Then, with a coarse well-chalked file, file the four faces of the tip to remove only the "tin" which is the coating of solder. The chalk on the file helps to keep bits of solder and copper from fouling the file teeth.

9292 1ese

The coating of solder is removed before the subsequent heating for forging, because it would otherwise cause deep pits to form in the surface of the copper when the copper is brought up to forging temperature. To forge, heat the copper to a dull-red heat by whatever means you have available, noting the color under a shaded light. If heated to a dull-red as viewed in sunlight or other bright light, it will have been overheated to a degree which will cause undesirable pitting of the surface.

Then, referring to figure 2-7-27, forge the copper to approximately the taper that is shown. Too long a taper causes the tip to cool too fast in use. Too short a taper does not produce enough surface area to transfer heat quickly from the copper to the work.

Figure 2-7-27.—Forging a soldering copper.

TINNING A SOLDERING COPPER

If a soldering copper is new or has just been forged, it will need to be tinned. To do so hold it in the vise and "dress" the point with a well-chalked file. By "dressing" is meant filing to remove hammer marks resulting from the forging process and to round off the sharp corners slightly. This is not always required when a tinned copper is to be retinned. Inspection will reveal if it is necessary. Then heat the copper hot enough so that it will readily melt solder. This temperature will be far below the dull-red forging temperature. Try melting solder with the copper frequently as it is being heated, and as soon as it will melt solder, it is ready for tinning.

To tin the copper, first quickly dip it into a jar of dipping solution as shown in figure 2-7-28. Dipping solution is made by dissolving a half

Figure 2-7-28.—Cleaning a soldering copper.

ounce of powdered sal ammoniac in a quart of clean water. If none is available in powdered form, scrape enough off a sal ammoniac block. Dip the copper quickly—in and out—and only an inch deep. This quick dip produces a puff of steam which, along with the chemical action of the solution, "blows off" any dirt and oxides present on the surface of the pointed end of the copper. Notice that the handle of the copper is held between the thumb and index finger with the copper hanging vertically downward. This affords good wrist action to assure a quick dip to remove the oxides without appreciably cooling the copper.

Then, with the copper cleaned (and still hot because it was dipped quickly into the dipping solution), rub each of its four faces on the sal ammoniac block as shown in figure 2-7-29, adding solder from a roll of solid wire solder or from a bar as indicated in this figure. The sal ammoniac will cause the solder to flow over the faces of the copper and tin them (coat them with solder). The coating is bright and shiny and very thin. It enables the copper, when in use, to pick up beads of solder which will adhere to its surface for transfer to the surface of the work being soldered. Another important function of this tinned surface is to aid in the rapid transfer of heat from the copper, through the tinning, to the work.

9293

Figure 2-7-29.—Tinning a soldering copper.

Should any scum or dirt picked up from the sal ammoniac block remain on the tinned copper after the tinning process, brush it off with a damp pad of cloth. The damp pad forms steam which, along with the rubbing contact of the pad, will leave the point of the tinned copper bright and clean and ready for use.

SOLDERS

Most soft solders are alloys of tin and lead. Occasionally antimony, silver, arsenic, or bismuth are added to give special properties to the solders. Solders used for joining aluminum are usually alloys of tin and zinc or of tin and cadmium. As mentioned before, soft solders have melting points below 800° F and below the melting points of the metals being joined. The melting points of most tin-lead solders range from about 360° F to about 465° F.

Tin-lead solders are usually identified by numbers which indicate the percentage of tin and the percentage of lead. The first number gives the percentage of tin, the second gives the percentage of lead. For example, a 30/70 solder is an alloy of 30 percent tin and 70 percent lead. A 50/50 solder (sometimes called half-and-half solder) is an alloy of 50 percent tin and 50 percent lead. A 15/85 solder is an alloy of 15 percent tin and 85 percent lead. Solders containing a high percentage of tin are more expensive than those containing a high percentage of lead. In general, the solders which contain a high percentage of tin have lower melting points than those which contain a high percentage of lead.

Solders are available in various forms, including bars, wires, ingots, and powders. Wire solder is available with or without a flux core.

FLUXES

To make a satisfactory joint, both the metal to be joined and the solder must be free of dirt, grease, oxides, and other foreign matter which would keep the solder from adhering to the metal. Fluxes are used to clean the joint area, to remove the oxide film which is normally present on any metal, and to prevent further oxidation. Fluxes also decrease the surface tension of the solder and thus make the solder a better wetting agent. Table 2-7-1 shows the fluxes that are generally used with some common metals.

Fluxes are generally classified as corrosive, mildly corrosive, and noncorrosive.

Table 2-7-1.—Fluxes Used for Soldering Some Common Metals.

Metals	Fluxes
Brass, copper, tin	Rosin
Lead	Tallow, rosin
Iron, steel	Borax, sal ammoniac
Galvanized iron	Zinc chloride
Zinc	Zinc chloride
Aluminum	Stearine, special flux

CORROSIVE FLUXES have the most effective cleaning action. However, any trace of corrosive flux that remains on the work will cause subsequent corrosion of the metal. Therefore corrosive fluxes are not used for soldering electrical connections and for other work in which subsequent corrosion would present a serious problem.

The most commonly used corrosive fluxes are sal ammoniac (ammonium chloride) and zinc chloride. These fluxes are frequently used in solution or in paste form. The solvent is evaporated as the work is heated, leaving a layer of solid flux on the work. At the soldering temperature, this layer of flux melts and partially decomposes, liberating hydrochloric acid. The hydrochloric acid dissolves the oxides from the surface of the work and from the solder.

Zinc chloride (sometimes called CUT ACID or KILLED ACID) should be made up in small amounts, as required for use. To prepare zinc chloride, pour a small amount of muriatic acid (the commercial form of hydrochloric acid) into a container. Then add pieces of zinc to the muriatic acid until the liquid no longer boils and bubbles when the zinc is added. The zinc and the

9294

SOLDERING SHEET METAL

One way to solder sheet metal is shown in figure 2-7-30. In figure 2-7-30A, you see flux being applied to a lapped seam with a small bristle brush. The flux is applied to both surfaces that are to come into contact, and both surfaces often must be mechanically cleaned first. This means that they must be filed, scraped, or cleaned with abrasive cloth until they are bright. The flux then cleans them chemically to remove oxides. In addition to cleaning the surface, the flux will retard further oxidation and help the solder to flow over the surfaces being joined. The usual flux for tinplate is rosin applied as a powder to be sprinkled on or as the core of rosin core wire solder. The usual flux for sheet metal having a coating of zinc (often called galvanized iron) is zinc chloride. This is an acid sometimes called "cut acid" or "killed acid" and is made by adding zinc, a little at a time to hydrochloric acid, until the acid stops working chemically on zinc. The acid is then said to be "cut" or "killed." A few extra pieces of zinc are usually added to be sure the action is completely stopped. After standing overnight, the liquid is poured through a rag to strain out the residue before it is used as a flux. Hydrochloric acid is known commercially as muriatic acid and sometimes as "raw acid."

Figure 2-7-30.—Soldering sheet metal.

If galvanized metal is being soldered, cut hydrochloric acid (zinc chloride) may be used as a flux only if the soldering is for the purpose of making the seam air- and water-tight. The mechanical strength of such a seam must be obtained by riveting or other means such as grooving the seam before the soldering is done. Soldering adds little to the strength of the seam because it adheres only to the coating of zinc (the galvanizing) which itself has very limited adherance to the base metal of the sheet. When strength is necessary, and mechanical means cannot be used, use muriatic acid instead of zinc chloride as a flux before applying the solder. This acid will remove the coating of zinc on the galvanized iron so that the solder can adhere directly to the base metal of the sheet and give a strong bond. Be very careful not to splatter muriatic acid on your clothing or on the job. If a drop of acid gets on the job where it should not be, it will remove the protective coating of zinc at that place. If this happens, be sure to flow a little solder over the metal to tin the area and restore the protection. Similarly, when using muriatic acid, be sure that you flow solder over the entire area of the base metal where the galvanizing has been eaten away to restore the protection to the metal. This is done while soldering, and means you sometimes must flow more solder on the base metal than would actually be needed for the seam.

When flux has been applied to both surfaces, put them together as shown in figure 2-7-30B. Place beads of solder along the joint by melting them off the end of a bar of solder right onto the joint or by melting them on the sal ammoniac block and putting them in place, after they have cooled, with your fingers. These drops or beads of solder will flow into the seam when the metal is heated.

Then, as shown in figure 2-7-30C, hold the metal together with a stick of wood (which is a good heat insulator) and place the heated copper with one face flat on the seam. The entire face must be in contact to provide the greatest possible flow of heat from the copper to the work. Hold it there until the nearest bead of solder begins to melt and flow, as it will, into and through the joint, forming a small fillet, as shown in the inset of figure 2-7-30, on both sides of the seam. In the insert the metal is shown as separated a bit only to indicate that the solder is continuous through the entire lapped seam. Then, maintaining contact with the metal, slowly draw the copper along the length of the seam at the speed necessary for it to melt the beads of solder. When the solder near the stick of wood freezes (solidifies), it will hold the joint and the stick can be moved ahead. Reheat the copper, or take another heated copper, when it no longer melts the solder readily.

Remember that the hot copper heats the metal which in turn melts the solder which

9296

then flows through the entire seam. Dropping solder along the seam by holding the copper against a bar of solder in the air a few inches above the seam is not good soldering. However, feeding the solder to the heated metal (heated with the hot copper) which you are soldering, from a coil of wire solder or a bar of bar solder, rather than placing beads along the seam, is another correct way of soldering.

A thorough washing with soda and water after the soldering is completed will remove any remaining flux and prevent corrosion that would otherwise occur.

SOLDERING AN ELECTRICAL CONNECTION

To solder electrical connections, figure 2-7-31, use rosin core solder. The reason for this is that acid core solder, or acid applied with a brush, is usually difficult or impossible to wash off electrical gear. Any acid flux that remains from the soldering operation causes subsequent corrosion which cannot be tolerated. When new wire is being soldered, no mechanical cleaning, such as scraping, is necessary. Old wire, which may have a heavy coating of oxide on its surface, or from which the insulation does not strip off cleanly, may need to be scraped with a knife until it is bright and clean.

Figure 2-7-31.—Soldering an electrical connection.

To solder electrical connections, hold the soldering iron (copper) beneath the splice being soldered with as much mechanical contact as possible to permit maximum heat transfer. Apply the rosin core solder to the splice. The tinning on the soldering iron aids the transfer of heat to the spliced wire which, when hot enough, will melt the solder. Before this temperature is reached the rosin core will have melted and run out over the wire to flux the splice. When the solder has coated the splice completely, the job is finished. No extra solder is needed.

NOTE.—The term "soldering iron" is used here because, when this tool is electrically heated with its own heating element, it is usually called an "iron" rather than a "copper." This type is generally used on electrical gear. However, both "iron" and "copper" are sometimes used interchangeably for the tool used for soldering.

TORCH SOLDERING

Torch soldering is often used for small jobs or for work which is relatively hard to reach. A gasoline blowtorch or an alcohol torch may be used for torch soldering.

The general procedure for torch soldering is to play the flames from the torch on to the surfaces to be joined and then apply cold solder in bar or wire form. The heated surfaces will melt the solder. As the solder melts, any excess solder should be wiped off with a damp cloth before it completely hardens.

SOLDERING BY SWEATING

Soldering by sweating is frequently used for making electrical connections. To make a sweated joint, clean and flux each surface to be joined. Then tin each surface. Hold the pieces firmly together and heat the joint with a soldering copper or with a torch until the solder melts and begins to run out. Remove the source of heat and hold the parts firmly in position until the solder completely hardens.

SOLDERING ALUMINUM ALLOYS

Soldering aluminum alloys is more difficult then soldering many other metals. The difficulty arises largely from the fact that aluminum alloys are always covered with a layer of oxide, the thickness of the layer depending on the type of alloy and the conditions to which it has been exposed.

Many aluminum alloys can be successfully soldered, however, if the proper techniques are used. Wrought aluminum alloys are usually—although not always—easier to solder than cast aluminum alloys. Heat-treated aluminum alloys are extremely difficult to solder, as are aluminum alloys containing more than 1 percent magnesium.

9297

The solders used for soldering aluminum alloys are generally tin-zinc or tin-cadmium alloys; they are usually referred to as ALUMINUM SOLDERS. Most of these solders have higher melting points than the tin-lead solders used for ordinary soldering. Both corrosive and noncorrosive fluxes are used for soldering aluminum.

The first step in soldering aluminum is to clean the surfaces completely and remove the layer of oxide. If a thick layer of oxide is present, remove the main part of it mechanically by filing, scraping, sanding, or wirebushing. A thin layer of oxide can often be removed by using a corrosive flux; the flux, of course, must be completely removed from the joint after the soldering is finished.

After cleaning and fluxing the surfaces, tin the surfaces with aluminum solder. Apply flux to the work surfaces and to the solder. You can tin the surfaces with a soldering copper or with a torch. If you use a torch, do not apply heat directly to the work surfaces, to the solder, or to the flux. Instead, play the torch on a nearby part of the work and let the heat be conducted through the metal to the work area. Do not use any more heat than is necessary to melt the solder and tin the surfaces. Work the aluminum solder well into the surfaces. After the surfaces have been tinned, the parts may be sweated together.

A procedure that is sometimes used for soldering aluminum alloys is to tin the surfaces with an aluminum solder and then to use a regular tin-lead solder to actually join the tinned surfaces. This procedure may be used when the shape of the parts prevents the use of the sweating method or when a large amount of solder is required to join the parts. When using tin-lead solder with aluminum solder, it is not necessary to use a flux.

Another method of soldering aluminum is by "friction soldering." In this method, a molten pool of solder is deposited on the aluminum. The surface of the aluminum underneath the molten pool is scratched so that the oxide coating is abraded and broken up. The oxide floats to the surface of the solder puddle. The solder then tins the bare aluminum surface from which the oxide has been removed. After such tinning, two aluminum surfaces can easily be joined by applying heat to melt additional solder on the tinned area to form a fillet or to fill the joint.

Although mill files, soldering rods, soldering copper points, and other tools or devices may be used to abrade the oxide film and remove it from the surface of the aluminum, the best device for this purpose is a glass fiber brush. The brush is very easy to use and is more effective than other tools in breaking up the oxide film. When a glass fiber brush is used, the friction soldering process produces better soldered joints than are produced by any other aluminum soldering process.

RIVETING METAL

After metal has been cut and formed, it must be joined together. Most sheet metal seams are either locked or riveted, although some are joined by brazing or welding. This section deals only with joining sheet metal seams by riveting.

SELECTING THE PROPER RIVET

Rivets are available in all of the common metals, in many lengths and in many diameters. Some of the standard head types are shown in figure 2-7-32.

Figure 2-7-32.—Some common types of rivets.

The proper length of rivet to use for a particular job is determined by adding to the grip one and one-half times the rivet diameter. (See fig. 2-7-33C.) This will provide enough metal to form a second "head" at the end of the rivet (fig. 2-7-33A) or to fill the countersunk portion of the hole for flush surfaces as shown in figure 2-7-33B. The grip, as shown in figure 2-7-33, is always measured from face to face of the work, regardless of the type of rivet.

To rivet metal, select the rivet of the proper metal, type of head, and length for the job, and the right diameter.

9298

rese

Figure 2-7-33.—Showing what is meant by "grip" of a rivet.

Table 2-7-2.—Guide for Selecting Rivet Size for Sheet Metal Work.

22	2 1/2
20	3
18	3 1/2
16	4

RIVETING SHEET METAL

For sheet metal work, you will probably use tinners' rivets more than any other kind. Tinners' rivets vary in size from the 8-ounce rivet to the 16-pound rivet. This size designation indicates the weight of 1000 rivets; thus, if 1000 rivets weigh 8 ounces, each rivet is called an 8-ounce rivet. As the weight per 1000 rivets increases, the diameter and length of the rivets also increase. For example, the 8-ounce rivet has a diameter of 0.089 inch and a length of 5/32 inch, while the 12-pound rivet has a diameter of 0.259 inch and a length of 1/2 inch. For special jobs that require fastening several layers of metal together, special rivets with extra long shanks are used. Table 2-7-2 is a guide for selecting rivets of the proper size for sheet metal work.

Rivet spacing is usually given on the blueprint or drawing that you are working from. If the spacing is not indicated, space the rivets according to the service conditions the seam must withstand. For example, if the seam must be watertight, you will need many more rivets per inch than if the seam does not need to be watertight. No matter how far apart the rivets are, there must be a distance of at least 2 1/2 times the rivet diameter between the rivets and the edge of the sheet, as measured from the center of the rivet holes to the edge of the sheet.

After you have determined the size and spacing of the rivets, mark the location of the centers of the rivet holes. Then pierce the metal by punching or drilling a small hole. The hole must be slightly larger than the diameter of the rivet to provide a slight clearance.

Riveting involves three operations: drawing, upsetting, and heading. These are illustrated in figure 2-7-34. A rivet set and a riveting hammer are used to perform these operations. The procedure for riveting sheet metal is as follows:

1. Select a rivet set that has a hole slightly larger than the diameter of the rivet.

2. Insert the rivets in the holes and rest the sheets to be joined on a stake or on a solid

Figure 2-7-34.—Drawing, upsetting, and heading a rivet. 11.295

9299

bench top, with the rivet heads against the stake or bench top.

3. Draw the sheets together by placing the deep hole of the rivet set over the rivet and striking the head of the set with a riveting hammer. Use a light hammer for smaller rivets, a heavier hammer for larger rivets.

4. When the sheets have been properly drawn together, remove the rivet set. Strike the end of the rivet LIGHTLY with the riveting hammer, to upset the end of the rivet. Do not strike too hard a blow, as this would distort the metal around the rivet hold.

5. Place the heading die (dished part) of the rivet set over the upset end of the rivet and form the head. One or two hammer blows on the head of the rivet set will be enough to form the head on the rivet.

A correctly drawn, upset, and headed rivet is shown in the top part of figure 2-7-35. The lower part of this illustration shows the results of incorrect riveting.

When it is necessary to rivet a seam in such a position that you cannot use a stake or a bench top to back up the rivet, a hand dolly may be used as shown in figure 2-7-36.

11.296

Figure 2-7-35.—Correct and incorrect riveting.

11.297X

Figure 2-7-36.—Using a hand dolly to back up rivets.

RIVETING A SEAM IN A CYLINDRICAL SECTION

To rivet a seam in a cylindrical structure such as the one shown in figure 2-7-37, use a hollow mandrel stake or some other suitable bar as backing for the rivets. The procedure for riveting a seam in a cylinder is as follows:

1. Insert rivets in the end holes, and slip the pieces over the stake or bar.

2. Draw the seams together and upset the end rivets enough to hold the structure together.

3. Insert the center rivet. Draw, upset, and head this rivet.

4. Complete the seam by riveting from the center to one end and then to the other end. Complete the drawing upsetting, and heading of each rivet as you work along the seam.

11.298X

Figure 2-7-37.—Riveting a seam in a cylindrical section.

RIVETING METAL, USING LARGE RIVETS

To rivet metal with rivets too large to permit the use of a rivet set, set the rivet by striking the metal around the rivet with a hammer (fig. 2-7-38) or by striking a punch (fig. 2-7-38B) while working it around the rivet to force the two pieces of metal together and against the head of the rivet. Then mushroom the rivet, as shown in figure 2-7-38C, using several flat blows if necessary with the face of the hammer. Finally, to give the mushroom a rounded form, work around it with the ball peen of the hammer, striking angled blows until a second head is formed (See fig. 2-7-38D.)

To upset (mushroom or flatten) rivets when the second head is to be a countersunk head, countersink the stock and insert the rivet as shown in figure 2-7-39A. After setting the

9300

Figure 2-7-38.—Riveting metal, using large rivets.

Figure 2-7-39.—Upsetting a rivet that is countersunk.

rivet, either with or without a rivet set, strike the rivet with the face of the hammer to force the metal into the countersunk hole. In figure 2-7-39B the rivet was just the right length to fill the countersunk hole. A too-short rivet will not fill the countersunk hole and a too-long rivet can be left slightly high or be filed, round, or otherwise cut flush with the surface if necessary.

STAMPING LETTERS AND FIGURES ON METAL

To stamp letters and figures on ferrous metal (cast iron or steel), first test it with a sharp mill file. If a sharp mill file will "take hold" and cut the metal, this indicates that the surface is soft enough to stamp without damaging the steel letters and figures used for stamping. Nonferrous metals are safe to stamp without testing. They are—even when heat treated—softer than the steel letters and figures.

Draw a guideline on the job and follow it as you stamp each letter and figure just above the line (See fig. 2-7-40.) Hold the steel letter or figure between your thumb and two fingers and strike only one blow for each impression. To determine how hard to strike the tool with the hammer, make a trial run on a test piece of the same metal.

Figure 2-7-40.—Stamping letters and rivets on metal.

APPENDIX I

TRAINING FILM LIST

Training films that are directly related to the information presented in this training course are listed below. Under each chapter number and title, the training films are identified by Navy number and title and are briefly described. Other training films that may be of interest are listed in the United States Navy Film Catalog, NavPers 10000 (revised).

PART I

Section 1

COMMON HANDTOOLS

MA-1929A — The Care and use of Hand Tools—Wrenches. Shows various types of wrenches, and explains how to use them. Stresses necessity for care of tools and gives some rules for best results when using them.

MA-1929B — The Care and use of Hand Tools—Pliers and Screwdrivers. Shown are uses, as well as misuses of pliers and screwdrivers.

MA-1929C — The Care and use of Hand Tools—Chisels. Explains characteristics of the various types and sizes of cold chisels. Demonstrates correct use of each type of chisel and cautions against dullness of points, cutting too deep, and improper care and use.

MA-1929D — The Care and use of Hand Tools—Hammers. Demonstrates various uses of the claw, ballpeen, crosspeen, and sledge hammers (which are classified as hard) and plastic wooden mallet, lead, brass, and rawhide type (which are classified as soft).

MA-1929E — The Care and use of Hand Tools—Punches, Drifts, and Bars. Describes and explains the use of: (1) Bars (crow, wrecking, pinch or pry); (2) Punches and drifts, (prick punch, center punch, tapered punch or drift pin, solid or starting punch, pin punch).

MA-1929F — The Care and use of Hand Tools—Hacksaws. Explains construction and function of hacksaws.

9302 10CE

PART I

Section 2

COMMON POWER TOOLS

MN-142 — Drilling in Metal, Wood, and Plastics. Points out six basic steps in drilling, and demonstrates how to lay out wood and plastics with drill press, electric drill, and hand drill.

MA-2087A — Hand Measuring and Power Tools—Operation and Care of Portable and Bench Grinders. Describes uses and shows operation of a bench grinder and a portable grinder. Precautions to be observed and stressed.

MA-2087B — Hand Measuring and Power Tools—The Portable Electric Drill. Demonstrates how to assemble and how to use 3/4" portable electric drill, and stresses importance of its care. Both straight photography and animation are used.

PART II

Section 1

MEASURING

ME-239A — Precision Measuring—The Steel Rule. Steel rule and its common divisions (1/64, 1/32, 1/16, 1/8 inch) is shown in its 6-inch type and in such special forms as hook rule, flexible rule, depth gauge, and combination square.

ME-239B — Precision Measuring—The Micrometer. Identifies parts of the outside micrometer caliper (frame, anvil, barrel with graduated scale, internal barrel screw, spindle), and explains its operation. Examples of various measurements are given, and importance of getting the "feel" of the micrometer is stressed.

ME-239D — Precision Measuring—Vernier Scale. Principle of the vernier is explained in detail, and use of the vernier on the micrometer caliper is demonstrated. Explained is the vernier caliper in sizes from 6 to 24 inches. Treatment of fine tools as a matter of professional pride is brought out.

PART II

Section 2

COMMON POWER TOOLS

MN-142 — Drilling in Metal, Wood, and Plastics. Points out six basic steps in drilling, and demonstrates how to lay out wood and plastics with drill press, electric drill, and hand drill.

MA-2087A — Hand Measuring and Power Tools—Operation and Care of Portable and Bench Grinders. Describes uses and shows operation of a bench grinder and a portable grinder. Precautions to be observed and stressed.

MA-2087B — Hand Measuring and Power Tools—The Portable Electric Drill. Demonstrates how to assemble and how to use 3/4" portable electric drill, and stresses importance of its care. Both straight photography and animation are used.

PART II

Section 6

METAL CUTTING OPERATIONS

ME1051A — Cutting Threads with Taps and Dies. Demonstrates hand cutting of internal threads with a tap, and hand cutting of external threads of a stud with a die. Discusses choice of drill, drilling hole, use of the three taps (taper, plug, and bottoming), removing a broken tap.

ME1051D — Reaming with Straight Hand Reamers. Demonstrates correct techniques for using straight fluted, spiral fluted, adjustable hand reamers for work on a two bearing shaft (cast iron) and timing gear (steel) with keyway. Explains chattering and its elimination. Shows difference between machine reamer and hand reamer. Shows how to measure reamer with a micrometer.

ME1051E — Reaming with Taper Hand Reamers. Demonstrates recommended techniques for reaming taper holes necessary when a taper pin is used to fasten a collar to a shaft, and other work of a similar nature. Explains how taper is determined and shows straight fluted and spiral fluted reamers.

ME1051H — Fundamentals of Filing. Describes importance of files and filing in work of the machinist. Stresses physical movements of the files and machinist's body in filing techniques. Shows various types of files (fine, bastard cut, medium, rough, single cut, and double cut). Demonstrates use of file card to remove chips from teeth of the file.

MA1929C — Chisels. Explains characteristics of the various types and sizes of cold chisels. Demonstrates correct use of each type of chisel and cautions against dullness of points, cutting too deep, and improper care and use.

9304

MA1929F	Hacksaws. Explains construction and function of hacksaws. Discusses many types, sizes, and uses of frames and blades and demonstrates correct procedure for sawing metal with the hacksaw. Set of the teeth in various blades is illustrated.
ME7296A	Cutting and Threading Pipe by Hand. How to use pipe cutter and pipe reamer, select and insert proper type in stock, thread pipe by hand, test threads for fit, prepare fitted pipe for delivery, and the care of hand tools. SB7296B is an accompanying film strip for this film.

APPENDIX III

ELECTRICAL SAFETY PRECAUTIONS

(Articles 60-21 through 60-45 of BuShips Technical Manual)

SECTION II. ELECTRICAL SAFETY PRECAUTIONS

60-21. NEED FOR SAFETY PRECAUTIONS

(1) Safety precautions must always be observed by persons working around electric circuits and equipment to avoid injury from:

(a) Electric shock.

(b) Short circuits caused by accidentally placing or dropping a metal tool, ruler, flashlight case, or other conducting article across an energized line. The arc and fire which can be so started on even relatively low voltage circuits may cause extensive damage to equipment and serious injury to personnel.

(2) That the danger of shock from the 450-volt a.c. ship's service system is reasonably well recognized by operating personnel is shown by the relatively few reports of serious shock received from this voltage despite its widespread use. On the other hand, a number of shipboard fatalities have been reported due to contact with 115-volt circuits. Despite a fairly widespread but totally unfounded popular belief to the contrary, low voltage (115 volts and below) circuits are very dangerous and can cause death where the resistance of the body is lowered by moisture and especially when current passes through the chest. Shipboard conditions are particularly conductive to severity of shock because the body is likely to be in contact with the ship's metal structure and the body resistance may be low because of perspiration or damp clothing. Extra care is therefore needed.

60-22. SAFETY

Electrical safety is an all-hands job. For this reason, it is essential that all personnel understand the lethal nature of the hazard and be made familiar with the electrical safety precautions and safe practices. Articles 60-21 through 60-40 should be required study material for all hands.

After an accident has happened, investigation almost invariably shows that it could have been prevented by the exercise of simple safety precautions which are then posted for future guidance, but which never undo the consequences of the accident that has gone before. Always observe safety precautions and keep accidents from happening. Always remember that:

(1) Electricity strikes without warning.

(2) Hurrying reduces caution and invites accidents.

(3) Taking time to be careful saves time in the end.

(4) Taking chances is an invitation to trouble.

(5) If you do not know the safe way, it pays to find out before exposing yourself to danger.

(6) Every electrical circuit, with but insignificant exceptions which definitely do not include circuits even as low as 35 volts and possibly even lower, is a potential source of danger and MUST BE TREATED AS SUCH.

(7) Except in cases of emergency, never work on an energized circuit. It must be considered that the circuit is energized until a personal check has been made to see that the switch is opened and tagged (See art. 60-36), and the circuit has been tested with a voltmeter, or voltage tester. (See art. 60-30).

(8) Energized switchboards are a great source of danger. No work shall be undertaken on switchboards (energized or deenergized) without first obtaining the approval of the Electrical or Engineer Officer. The Commanding Officer's approval shall be obtained prior to the commencement of work on an energized switchboard.

(9) Records show that seven out of ten victims of electric shock were revived when artificial respiration was started in less than 3 minutes after the shock. After 3 minutes the chances of revival decrease rapidly.

9312

2317

All shipboard personnel should be made aware of the fact that a victim rendered unconscious by electric shock should receive artificial respiration and that it should be started in a matter of seconds rather than minutes. To this end the person nearest the victim should start the resuscitation without delay and call or send others for assistance and medical aid. The only logical permissible delay is that required to free the man from his contact with the electricity in the quickest, safest way. This step, while it must be taken quickly, must be done with great care, otherwise there may be two victims instead of one. This should be done in the case of a portable electric tool, light, appliance, equipment, or portable outlet extension by turning off the bulkhead supply switch or by removing the plug from its bulkhead receptacle. If the switch or bulkhead receptacle cannot be quickly located, the suspected electric device may be pulled free of the victim by grasping the insulated flexible cable to the device and carefully withdrawing it clear of its contact with the victim. Other persons arriving on the scene must be clearly warned not to touch the suspected equipment until it is unplugged. Aid should be enlisted to unplug the device as soon as possible. Where the victim is in contact with stationary equipment such as a bus bar or the contacts on a machine, he should be pulled free if the equipment cannot be quickly deenergized, or if considerations of military operation or ship survival prevent immediate shutdown of the circuits. The man can be quickly and safely cleared from his contact with the electricity by carefully applying the following procedures:

In pulling him free, the principles reflected by the safety instructions of article 60-37 must be kept in mind. To save time, however, the equivalent of the protective insulation for the rescuer must be improvised. For example, instead of taking time to hunt for a pair of rubber gloves for use in grasping the victim, the victim can be safely pulled free if conditions are dry by grasping him by slack in his clothing or by the leather of his shoes. Instead of hunting for a rubber mat on which to stand, such nonconducting materials as deck linoleum, a pillow, blanket, mattress, dry wood, or coil of rope will suffice. In no case during the rescue should any part of the rescuer's person directly touch hull metal or metal structure or furniture.

(10) Additional information on safety is to be found in "Electric Shock—Its Causes and Its Prevention," NavShips 250-660-42.

60-23. GROUNDED CIRCUITS A HAZARD

Keep electrical circuits which are not intentionally grounded clear of accidental grounds. When a man makes contact with the ungrounded side of a grounded circuit, a current can flow from the ungrounded side through the man to ground and back to the grounded side of the circuit. If neither side of the circuit is grounded, a man who makes accidental contact with a bare conductor on one side of a circuit will be in series with the insulation resistance on the other side of the circuit and the danger of receiving a severe shock will be less when the insulation resistance is high than when it is lowered by the presence of accidental grounds. The insulation on the other side of the circuit should not, however, be relied upon as a protection against shock, and great care should always be exercised to avoid contact with bare conductors. When circumstances make it necessary to work on live conductors or equipment, be sure to observe the precautions of article 60-37.

60-24. GROUNDING OF METAL PARTS AS A SAFETY MEASURE

Metal enclosing cases, bases, frames, and structural parts of electrical equipment which are not intended or expected to operate at potentials above ground potential should be grounded. Normally on steel-hull vessels such grounds are inherently provided because the metal enclosing cases or frames are in contact with one another and the metal structure of the vessel. Where such inherent grounding is not provided by the mounting arrangements, for instance, equipment supported on shock mounts which insulate it from the hull, and on wooden hull vessels, ground connections should be provided to ground the frame, enclosure, or support of all permanently installed electrical equipment and of all semiportable equipment which is normally used at a fixed location in the vessel. For the grounding of portable equipment, see articles 60-25 to 60-27 and 60-29. If enclosing cases and similar parts are not grounded, a breakdown of insulation may raise them to line voltage and create a hazard which is the more serious because it is unexpected. Such breakdowns from a circuit or machine to an ungrounded metal object will not be shown by ground tests or measurements of insulation resistance. They will be if the metal object is grounded.

9313

60-25. GROUNDED TYPE PLUGS AND RECEPTACLES FOR PORTABLE TOOLS AND EQUIPMENT

Navy specifications for portable tools require the electric cord for the tool to be provided with a distinctively marked grounding conductor in addition to the conductors for supplying power to the tool. Except for a few cases in which black was used in the cords for some items of portable equipment, past practice was to use red for the grounding conductor in three-conductor cables for portable tools and equipment, and green in four-conductor cables. Revised specifications require that green be used for the grounding conductor in cables for all new portable tools and equipment. The end of the grounding conductor which is within the tool should be connected to the metal housing; the other end should be grounded, that is, connected to the ship's metal structure. In order to provide a convenient means of connecting the grounding conductor to ground, the Bureau has standardized on the use of grounded type plugs and receptacles which automatically make this connection when the plug is inserted in the receptacle. The installation of grounded type receptacles has been authorized for all power outlets in surface vessels and for submarines. Where the grounded type receptacles have been installed, they should be used in conjunction with grounded type plugs (art. 60-27) to ground portable tools and equipment.

60-26. INSTALLATION AND TESTING OF GROUNDED RECEPTACLES

(1) General. If grounded receptacles have not yet been installed, the proper receptacles should be selected from the Navy Stock List of Shipboard Electrical Items and requisitioned through the cognizant symbol A supply system. See article 62-17 for information on the proper type of receptacle to obtain and the locations where receptacles should be installed.

(2) Making connection to ground. The types of grounded receptacles listed in article 62-17 have metal cases which are connected internally to the ground terminal of the receptacle. Grounding the case of the receptacle will ground the grounded terminal. There are still in use, however, some grounded receptacles with plastic cases. All such grounded receptacles should be inspected to make sure that the conductor used to connect the grounded terminal to ground has a cross section greater than the cross section of the line conductors which carry power to the receptacle. When this inspection is made, the receptacle should also be tested in accordance with article 60-26(5). An entry should be made in a record book kept for grounded receptacles giving the date when the inspection and test were made.

(3) Precautions to ensure alinement. It is dangerous to insert a grounded plug in a grounded receptacle in any way but the right way. For this reason, grounded plugs and receptacles are so designed that the plug must be rotated to the correct position before it can be inserted into the receptacle. The inside of the first types of grounded receptacles installed on board ship contained a phenolic polarity pin located to match with a groove in the plug and prevent the insertion of the plug in any but the correct position. In time, however, these phenolic polarity pins may become damaged or loosened to such an extent that they no longer perform their function. When the plug is badly worn or the polarity pin is loose or missing, an inexperienced operator can force a grounded plug into a grounded receptacle in the wrong position. The ground contact on the plug will then touch a live contact in the receptacle. The result is that the metal casing of the tool or equipment becomes a live conductor and sets up the possibility of a serious electric shock when the operator touches the equipment. In 1950 an improved alinement feature was designed for grounded plugs and receptacles to overcome this weakness. A guide to match the cross section of the plug, molded of insulating material, was placed in the receptacle opening in the cover of the receptacle. A sturdy metal polarity tab shaped to match the groove in the plug was brazed inside the metal cover to reinforce the molded guide in the receptacle opening. This improved cover design ensures that the plug is properly alined before it reaches the interior fittings of the receptacle, saving the wear and tear on the polarity pin that was previously encountered. All Navy stocks of plugs, receptacles, and receptacle covers were modified to incorporate the improved features. In 1950, authorizations were issued to ships to modernize shipboard plugs and equipment with the new parts. To make the improved grounded plugs and receptacles fully effective as a safety measure, the following precautions must be observed:

(a) The plug must be correctly connected to the tool or equipment.

(b) The receptacle cover must be placed so that the pointed metal polarity tab brazed

9314 9313

to the cover is superimposed over the phenolic polarity pin within the receptacle.

(c) The phenolic plug-guide insert in the aperture of the receptacle must be firmly in place. If a plug-guide is missing from the aperture of a receptacle, the plug of a portable electric tool or equipment can be incorrectly inserted. If inadvertently inserted when rotated 90° from its normal alinement with the contacts inside the receptacle, the grounding contact on the plug tip can touch a live contact in the receptacle. Since the grounding conductor in the tool cord provides a direct connection between the metal housing of the tool and the grounding contact on the plug, line voltage would be placed on the shell of the tool or equipment, thereby exposing the operator to possible electric shock. Receptacles should be inspected to make sure that the plug-guide inserts are neither missing nor loose to the extent that they can be pulled out manually. Where the inserts are missing, the entire cover should be replaced. Loose inserts in receptacle covers in use or drawn from stock should be corrected by cementing.

(4) Interim safety measures. If the grounded plugs and receptacles on a ship have not yet been modernized with the positive plug positioning features described above, the following interim precautions should be observed:

(a) Personnel should be instructed that before they insert a plug in a receptacle, they must make sure that the plug is rotated to such a position that its groove is alined with the polarity pin inside the receptacle. To facilitate carrying out this instruction, suitable markings may be painted on the plug tip and receptacle cover to show when the plug is properly alined.

(b) Inspections should be carried out to make sure that polarity pins in receptacles are not missing, bent, or worn, and that plugs are in good condition.

(c) The preceding precautions apply to any electrically operated equipment with metal case, such as a coffee percolator, which is plugged into a receptacle.

(5) Test at installation. A test to determine whether the connections are correct should be made whenever a grounded receptacle is installed, repaired, or modified in any way. This test should be made as follows:

a. Receptacles-Navy Type - Drawings 9-S-4223-L (Modified), 9000-S6202-73310, 9000-S6202-73312, 9000-S6202-74026, and 9000-S6202-74068.

(1) Deenergize circuit, test to make sure that the receptacle is deenergized, and adopt all necessary precautions to make sure that it will stay deenergized until all tests at the receptacle, including (5) and (6) below, have been completed.

(2) Remove box cover and examine for the following:

(a) Correct type (see drawing numbers) having ground contact and diamond shaped polarity pin opposite. Replace if not of the proper type; see article 62-17 (1) through (10) for guide in recognizing obsolete types.

(b) Correct wiring.

(c) Secure terminal screws.

(d) Clean ground contact.

(3) Using a volt-ohmmeter, test the resistance from ships hull to face of ground contact (must be less than one ohm).

(4) Replace cover in proper relation to polarity and index pin.

(5) Insert type D-2-G Navy plug attached to an equipment or an adaptor, drawing 815-1197085. If an adapter is used, insert a commercial plug attached to an equipment into adaptor receptacle.

(6) Using a volt-ohmmeter, test resistance from housing of equipment to ships hull (must be less than one ohm).

b. Receptacles — Bladed —single outlet (used in lighting fixtures) and double outlet, drawings 9000-S6202-73274 and 9000-S6202-74263 and single, watertight outlet 9000-S6202-74456.

(1) Deenergize circuit, test to make sure that the receptacle is deenergized, and adopt all necessary precautions to make sure that it will stay deenergized until all tests at the receptacle, including (5) and (6) below, have been completed.

(2) Remove box cover and examine for the following:

(a) Correct type having two parallel slots and one U-shaped ground hole. Receptacle unit (drawing 9000-S6202-73274) having a blade type ground contact shall be replaced with duplex receptacles unit (FSN G-5935-283-4003). Single receptacle unit is installed in lighting fixtures shall have two parallel slots and one U-shaped ground hole. Replacements should be purchased from local suppliers.

(b) Correct wiring.

(c) Secure terminal screws.

(d) Clean ground contacts

9315

(e) Corrosion protection caps authorized for use in crew's heads and showers.

(3) Using a volt-ohmmeter, test the resistance from ships hull to the face of the ground contact (must be less than one ohm).

(4) Replace cover..

(5) Insert commercial grounded plug attached to equipment.

(6) Using a volt-ohmmeter, test resistance from housing of equipment to ships hull (must be less than one ohm).

(6) Test of grounded receptacles. To ascertain whether vibration, corrosion, or some other cause has made a grounded receptacle unsafe, each grounded receptacle on a ship should be inspected and tested in accordance with article 60-26 (5). These tests should be performed as follows:

a. Receptacles

(1) Detailed procedures. It is recommended that the detailed procedures as outlined in article 60-26 (5) regarding receptacles be performed once on each ship, and thereafter be repeated only following an overhaul or other period during which derangement of these receptacles could have occurred.

(2) Abbreviated procedure:

(a) It is recommended that the following procedure be employed in making a routine ground continuity of each installed receptacle at least once a month.

1. Plug in any small 115 volt portable electric tool into the receptacle to be tested.

2. Secure one ohmmeter lead to the metal of the tool housing and the other lead to the ships hull.

3. The ohmmeter reading must be less than one ohm to indicate a satisfactory grounding circuit from the equipment housing through the plug and receptacle to the ships hull.

(b) Unsatisfactory receptacles should be immediately repaired or be tagged to indicate that they must not be used.

(c) A record book should be kept on each ship giving the location of all grounded receptacles and the dates when they have been tested.

60-27. PLUGS AND CORDS

(1) Cords for use with grounded plugs. Some of the portable tools now in use on Naval vessels may not yet be provided with the grounded type plug. In addition, there is a wide range of miscellaneous portable electric equipment that may be issued without being provided with a cord that has a grounding conductor and a grounded plug. This equipment includes galley equipment (fruit juice extractors, food-mixing machines, coffee pots, toasters); office equipment (adding machines, addressograph machines); shop equipment (key duplicating machines, valve grinders, mica undercutters, hot plates); medical equipment (infrared lamps, ultra-violet lamps, sterilizers); barber shop equipment (hair clippers); laundry equipment (flatirons); and others. Except as indicated in article 60-27 (2) and (3):

(a) All 115-volt or 230-volt single phase a.c. and all 115-volt or 230-volt two-wire d.c. electrically operated equipment now on board ship which does not have a cord with a grounding conductor and grounded plug, and all such equipment subsequently issued to the ship without a cord which has a grounding conductor and grounded plug, should be provided with a three-conductor flexible cable with standard grounded plug. The three-conductor flexible cable should be type SO or ST color coded black, white and green, as listed in the Navy Stock List of General Stores, Group 61. For general use, the plug should be the bladed type with "U"-shaped grounding prong. These are stocked for small and large diameter cords under numbers G5935-280-2380 and GS935-280-2381. Stub-type plugs which can be made watertight when in use, formerly designated as type D-2-G, drawing 9-S-440-L, are now furnished with plastic shell. They are identified by Bureau of Ships drawing 815-1197805, and the symbol numbers 701.1 or 720 for small and large diameter cords respectively.

(b) All 115-volt 3-phase electrically operated portable equipment now on board ship or subsequently issued, which does not have a cord with a grounding conductor and grounded plug, should be provided with a type FHOF four-conductor flexible cable color coded black, white, red, and green, with standard Navy grounded plug, type EEE-125, shown on Bureau of Ships plan 9-S-4861-L.

(c) The length of the cord for portable tools should be 25 feet. The length of the cord for such equipment as heaters should be as required. Extension cords (shown on Bureau of Ships plan 9000-S6202-73448) for use with portable tools and equipment are authorized for inclusion in the ship's allowance. These extension cords consist of 25 feet of three-conductor flexible

9316

cable (which includes the grounding wire) with a grounded plug attached to one end and a grounded type portable receptacle suitable for receiving the grounded type tool or equipment plug on the other end.

(2) No change to be made just for the sake of color coding. No change should be made in equipment now on board ship or subsequently issued which has a cord with a grounding conductor color coded in conformity with past practice. Such equipment should be used in accordance with past practice until cord replacement becomes necessary. Replacement cable should be type SO or SI for three-conductor cords, and type FHOF for four-conductor cords. The green conductors should be used for the grounding conductor. The plugs for three-conductor and four-conductor flexible cable are provided with a gland nut and packing which grips the cord securely and should prevent the cord from being pulled out of the plug under most conditions of rough usage.

(3) Cords not to be replaced on equipment that is adequately grounded. The cords need not be replaced on apparatus that is positively and adequately grounded through its mounting, nor on portable lights and other equipment having no exposed metal parts that may become energized. A two-conductor flexible cable and a plug suitable for use with the grounded type receptacle should be provided for such equipment. In addition, a check should be made to make sure that the natural grounding of the equipment is not blocked off in any way. For example, it was found that in one type of 8 1/2-inch bracket fans used on submarines and smaller surface ships, the fan motor case is insulated from the fan base by a vibration mount. All fans of this type should be provided with a stranded ground connection from the motor case to the mounting bracket. Be sure to unplug all equipment grounded by direct contact with mountings or by a ground connection to mountings, before removing the equipment from mountings or disconnecting the ground connection; otherwise the ground is lost while the equipment and its case may still be a dangerous potential. Another method of ground consists of replacing the two-conductor cable from the base to the motor with a three-conductor cable. Two of the conductors are for carrying power to the motor; the third should be connected to the motor case at one end and to the mounting bracket at the other end. Electric shavers may be grounded where feasible and if desired by the owner.

(4) Connecting cords and plugs. In connecting the cord and plug, the grounding conductor of the cord should be connected to the ground contact of the plug at one end, and to the metal equipment casing at the other. Extreme care must be exercised to see that the ground connection is made correctly. If the grounding conductor which is connected to the metallic equipment casing is inadvertently connected to a line contact of the plug, a dangerous potential will be placed on the equipment casing. This might easily result in a fatal shock to the operator. To guard against this danger, the connections should be tested after they have been made as described in article 60-27 (5).

(5) Tests of plug connections. Before using portable electrical equipment for the first time, check the plug connections of the equipment for correct wiring. The following tests of portable equipment should be conducted in a workshop equipped with a nonconducting surface workbench and diamond tread rubber deck covering. Electricians making the tests should wear rubber gloves during tests.

(a) Plug—NAVY TYPE.—Drawing 9-S4440-L, Type D-2-G, or 815-1197085 symbols 701.1 and 720.

1. Examine and make sure that insulation and contacts are in good condition.

2. Examine and make sure that conductors are properly secured under terminal screws.

3. Examine to determine that the plug is clean and that all contacts are free of hangover fringes of moulding material that would prevent making good contact. Particular attention should be given to the ground contact.

4. Using a volt-ohmmeter, test resistance from ground contact to equipment housing (must be less than one ohm). Move or "work" cable with a bending or twisting motion. A change of resistance will indicate broken strands in the grounding conductor. If this is found, the cable must be replaced.

Check type D-2-G plug on equipment and extension cord. Using a megohmmeter, measure insulation resistance between brass shell and each contact on plug. Move or work cable with a push-pull, bending and twisting motion while taking reading. If resistance is less than one megohm, check for twisted bare wires in plug. Rewire defective plug and replace brass shell with nylon shell. If excessive wear and tear requires a plug to be replaced, accomplish by renewal of plug tip and replacing brass shell

9318 9317

of plug with nonconducting plastic (nylon) plug shell. Do not re-use brass shells. Nylon plug shall is identified as drawing NR815-1,197,085, stock number H5935-678-8520 for cables up to 0.425-inch diameter, and H5935-732-1841 for 0.560-inch diameter cables. If nylon plug shell is not in stock, rewire and retest brass-shell type plug for temporary use until nylon plug shell is available.

(b) Plug—Bladed.—Round or U-shaped contact.

1. Examine to determine that insulation and contacts are in good condition.

2. Examine and make sure that conductors are properly secured under terminal screws.

3. Using a volt-ohmmeter, test the resistance from ground contact to equipment (must be less than one ohm). Move or "work" cable with a bending or twisting motion. A change of resistance will indicate broken strands in the grounding conductor. If this is found, the cable must be replaced.

(6) Workmanship in connecting cords to plugs, tools and extension receptacles. The cord conductors must be fastened securely and in a workmanlike manner to the terminals of the plug, tool, or extension receptacle. There must be no loose conducting strands which might make accidental contact with metal parts they should not touch. Sucy loose strands, if present, might place line potential on the metal shell of the plug when the plug is partially inserted in an energized receptacle. A fatal hand-to-hand electric shock can result if the receptacle is on the end of an energized extension cord and has its metal case raised to line potential (of opposite polarity to that on the shell of the plug) by loose conducting strands at the cord connection to the receptacle. The following precautions should be observed:

(a) The cord conductors must terminate in a standard crimp or solder type wiring terminal. Where the standard terminal is not practical, each conductor must be twisted tightly together and formed into an eyelet, (or a hook where the terminal screw is not removable, and dipped in or coated with solder to hold all strands tight.)

(b) Connections to all cords should be examined to make sure that they comply with paragraph (a), preceding. Nonconforming devices should be taken out of service until corrected.

(c) The connections to the cord on each portable tool, equipment, or extension receptacle repaired on board or delivered to the ship should be examined for compliance with the preceding requirements before the equipment is used. The tests on the individual devices prescribed in article 60-27(4)(a) do not reveal this defect when the devices are tested individually.

(7) Precautions in use of extension cords. Because a metal hull ship is a hazardous location, personnel who must use portable electric devices connected to extension cords should take the time to plug the device into the extension cord before the extension cord is inserted into a live bulkhead receptacle. Likewise, the extension cord should be unplugged from the bulkhead receptacle before the device is unplugged from the extension cord. Only approved extension cords of the type described in paragraph (1) (c) shall be used.

(8) Portable equipment and associated extension cords. Prior to issue of any portable electrical equipment, the attached cable with plug (including extension cords, when used) should be examined visually to assure satisfactory condition. (Tears, chafing, exposed insulated conductors, and damaged plugs are causes for cable or plug replacement.) Prior to issue of any portable electrical equipment, the item, with associated extension cords connected, should be plugged into a dummy (or deenergized) receptacle and tested for resistance from equipment housing to ship's structure, using a volt-ohmmeter (must be less than one ohm). Move or "work" cable with bending or twisting motion. A change in resistance will indicate broken strands in the grounding conductor. If this is found, the cable must be replaced. It is further suggested that, at the discretion of the Commanding Officer, a list be established of portable equipment requiring testing more or less often than once a month depending on conditions in his ship, and that the following items be considered for inclusion:

(a) Portable hand held electric tools that are permanently charged out, or are on loan to other shipboard departments or divisions should be tested once a week.

(b) Electrical equipment which is frequently touched, such as hot plates, coffee makers, toasters, portable (115 volt) vent sets, and movie projectors should be tested once a week.

(c) Electric equipment which is frequently touched such as bulkhead mounted (115

9318

volt) fans energized from receptacles, should be tested once a year.

(d) Electric equipment which gives a reading through the grounding circuit higher than 1 ohm should not be used until repaired. In addition the following tests shall be made:

NOTE: While testing portable equipment, frames are to be installed from ship's hull during test.

Insulation resistance. For this test a megohmmeter shall be used with one lead of the instrument connected to the metal can of the tool, and the other to one line terminal of the plug. Measure the resistance when the switch of the tool is ON and also when it is OFF. Repeat the tests with the instrument lead connected between the metal case of the tool and the other line terminal of the plug. In all cases, the measured resistance will be the normal insulation resistance (usually well in excess of one megohm) if the connections are correct.

(9) Reenforcement of flexible cable at junction with portable equipment. Reenforcement usually consists of a molded rubber sleeve. Examine to insure that sleeve is sound and free of cracks. Reenforcement consisting of coiled metal spring is dangerous since it can conceal broken cable insulation and exposed conductors. Replace spring coil with rubber or other suitable nonconducting sleeve.

(10) Extension cords, 25-foot, single outlet and 6-outlet (drawings 9000-S6202-73448 and 9000-S6202-74163). Check each extension in accordance with the procedures listed for plugs, receptacles and cables in articles 60-26(5)(a); 60-27(5)(a) (except 3) and 60-27(3).

60-28. PERSONAL EQUIPMENT - RADIOS, TELEVISION SETS, RECORD PLAYERS, WIRE OR TAPE RECORDERS, ELECTRIC SHAVERS, LIGHTS, FANS, TOOLS, AND HOBBY EQUIPMENT

(1) Personal radios, television sets, record players, and wire or tape recorders having metal cases or metal back or bottom are a safety hazard in many cases. In much of such equipment the chassis forms a part of the circuit and the exposed metal parts are energized, thereby creating the danger of shock to personnel touching them. Moreover, grounding these metal parts to the ship's structure would place a ground on the 115-volt lighting system contrary to the safety instructions. Consequently, the use of such equipment on board ship should not be permitted unless the equipment meets the requirements of article 60-28(5), and also unless it satisfies one of the following conditions:

(a) The equipment has a built-in power transformer which completely insulates the primary or line side of the transformer from the secondary or equipment side. The isolation of the primary and secondary sides of the transformer must never be inferred merely from the presence of the power transformer but must be checked by measuring the insulation resistance from each line terminal of the transformer to the chassis and exposed metal parts of the equipment. If the insulation resistance is of the order of several megohms, the equipment should be provided with a grounded plug and suitable cord, the grounding conductor of the cord being connected to the chassis and exposed metal parts of the equipment at one end and to the ground contact of the plug at the other end. This arrangement will ground the chassis and exposed metal parts of the equipment but will not ground the power supply.

(b) If the equipment does not have a power transformer which isolates the primary and secondary sides as described above, an isolation transformer must be installed (at the owner's expense) to perform this function. A grounded plug and suitable cord should be used with the grounding conductor of the cord connected to the chassis and the power conductors of the cord connected to the primary of the isolation transformer.

(2) Electric shavers. In general, the molded housing on an electric shaver is a nonconducting plastic material, and the cutting blades are isolated from any contact with the electrical components within the shaver. For this reason, 3-prong grounding plugs are not required on electric shavers. For safe use aboard ship, your electric shaver should have a completely insulating housing and isolated cutting blades, and the housing and cord must be free of cracks. If in doubt whether your electric shaver complies, have it checked by the electric shop. If your electric shaver falls in a wash bowl of water, let it go. Do not touch it without first unplugging the cord from its receptacle connector. Do not try to energize it. Take it to the electric shop for a safety check first.

(3) Personally owned electric lights, fans, tools. Personally owned or non-Navy standard electric lights, fans, and tools are not justified. They are generally a shock hazard because of inferior insulation, leakage currents, and flimsy

0320 9319

structure. Periodic inspections should be made to eliminate them from the ship. Adequate numbers and types of Navy lights, fans, and tools are available to meet all needs.

(4) Hobby Equipment. Personally owned hobby equipment such as hand-held, motor-driven carving tools are frequently found to be of flimsy construction and unsafe for use aboard ship. Such equipment may be retained aboard ship as an exception to article 60-28(3) subject to the following precautions:

(a) Prior to permitting use of portable, electrically operated hobby devices aboard ship, they should be inspected and tested by the electrical gang. Equipments which pass this inspection should be tagged as safe, giving date of inspection. This equipment should be frequently reinspected, at least once each 6 months.

(b) At any time that the hobby tool is damaged or is obviously defective, that is, if molded housing, cords, or plugs contain cracks or breaks or if the cord insulation breaks when sharply bent, the tool must not be used until repaired and reinspected by the electrical gang.

(5) No personal electrical equipment, such as radios, television sets, record players, wire or tape recorders, or other personal appliances as listed above, shall be used aboard ship without the Engineering Officer's tag of approval. Periodic inspection should be made to enforce this vital safety regulation.

60-29. GROUNDING PORTABLE TOOLS AND EQUIPMENT WHERE GROUNDED TYPE PLUGS AND RECEPTACLES ARE NOT INSTALLED

If the grounded type receptacles have not yet been installed in the spaces where the tool or equipment is to be used, other types of plugs and receptacles may be used if the grounding conductor in the tool or equipment cord is connected to the ship's metal structure by other methods; for example, by means of a spring clip or by securing the grounding conductor to a convenient screw or bolt. In those cases where the tool or equipment cord does not include an extra conductor for grounding, an additional conductor should be obtained and connected between the metal housing of the tool or equipment and the ship's metal structure. The additional conductor used to ground the case of the equipment must be of ample cross-sectional area and current-carrying capacity in order to be effective. It should have a cross section ay least equal to the cross section of the power conductors in the tool or equipment cord, and preferably greater. If the tool or equipment housing has two or more metallic parts which are not electrically connected, each should be connected to the grounding conductor. Care should be taken to secure a good contact between the grounding conductor and the metal to which it is connected, by scraping any paint away and scratching a clean surface. The ground connection should be made before inserting the power supply connecting plug, and the plug should be removed before removing the ground connection. Frequent inspection and check of the connections within portable electric tools and equipment should be made to insure that the supply cord and its connections are suitably insulated and that the ground connection is intact.

60-30. TESTING LEADS TO SEE IF ALIVE

All electrical leads are to be considered as being alive until it is positively proved that they are dead. To check a circuit, test the live side with a voltmeter or voltage tester, then test the dead side with the same device and retest the live side. This is to make sure the testing device is in good condition. Opening a switch to kill the power circuit does not always kill associated meter or remote control circuits. Always test such circuits in addition to testing the power circuit.

60-31. NEVER TAKE A SHOCK INTENTIONALLY

Intentionally taking a shock from any voltage is always dangerous and should not be done. Whenever it is necessary to check a circuit to see if it is alive, a voltmeter, voltage tester, or other suitable indicating device shall be used.

60-32. NEVER IMPLICITLY TRUST INSULATION

Never implicitly trust the insulation on live circuits when considering personnel safety. Insulation may look perfect, yet still not prevent a shock. Sufficient leakage current may be present to cause a fatal shock.

60-33. PORTABLE CABLES

(1) Portable cables should be carefully selected and maintained. They should be of the proper length and cross-sectional area. Spliced portable cables are extremely dangerous and should not be used unless an emergency warrants the risk involved.

9320

(2) Always support portable cables above decks, floor plates, and gratings. Never place them where they can be damaged by falling objects, by being walked on, or by contact with sharp corner or projections in the ship's hull or other objects. Where portable cables are passed through doorways or hatches, stops should be provided to protect the cables from being pinched by a door or hatch cover.

60-34. REPLACEMENT OF FUSES

(1) Fuses are safety devices and should be used as such. When a fuse blows, it should be replaced with a fuse of the same rated voltage and ampere capacity. Never short out a fuse.

(2) Fuse pullers made of insulating material should be used for the removal or replacement of fuses, except where, as is usually the case on I.C. and F.C. switchboards, the fuses are mounted in plug-type fuse holders. These fuses are removed by unscrewing the plugs.

(3) Only fuses of 10-ampere rated capacity or less should be removed from or replaced in energized circuits.

(4) Fuses larger than 10-ampere rated capacity should be removed or replaced only when the circuit is completely deenergized. After the replacement, the circuit should be energized only when the cover over the fuses is closed. Neglect of this precaution has led to injuries caused by explosion of a fuse when the circuit was energized.

60-35. SAFETY PRECAUTIONS WHEN SWITCHING

(1) Circuit breakers and switches should be operated with care for the safety of the operator and other personnel. Before closing any circuit breaker or switch, be sure that:

(a) The circuit is ready with all equipment connected to it in condition to be energized.

(b) Men working on the circuit are clear and are notified that it is to be energized.

(c) All circuit protective devices (fuses, circuit breakers, etc.) are in good working condition.

(2) When operating a circuit breaker or switch:

(a) Use only one hand except where the operating arrangements specifically provide for the use of both hands. Keep the other hand clear. Metal parts of circuit breakers may be at circuit potential.

(b) For manually operated knife switches, etc., make the closing or opening motion positive and rapid.

(3) In the case of switches enclosed in watertight cases, for example, snap switches and multipole rotary switches, the chief precaution required is to make sure that the switch has been operated to the position actually intended. Several reports have been received indicating that the switch handle was not operated far enough when the operator intended to transfer a circuit from one control station to another. Consequently, the switch contacts were left in an in-between position and the circuit was actually opened, thus leading to the possibility of serious casualty. The trouble was traced to the fact that gland rings in the switches had been tightened to a point where the friction on the switch shaft was so great that the action of the switch detent mechanism was no longer evident to the operator, with the result that he had no definite guide to ensure the proper positioning of the switch handle. The Bureau is studying this problem and is endeavoring to take corrective action as soon as possible by using improved types of packing and a type of construction which will ensure that the switch is watertight and that the amount of fraction on the shaft cannot be made excessive. In the meantime, all switches should be examined periodically to make sure that the shafts turn freely and the packing is the latest type specified by the Bureau. Personnel should be cautioned to make sure that switch handles are operated to the proper positions and that the switch is not sticking in an in-between position.

60-36. DEENERGIZE AND TAG CIRCUITS

(1) Work should not be done on any energized circuit, switchboard, controller, or other piece of electrical equipment unless the urgency of the work, together with the vital importance of the equipment concerned, dictates its necessity. Circuits to be overhauled or repaired should be deenergized by opening all switches through which the power could be supplied, and the circuit should be tested with a voltmeter or voltage tester (see art. 60-30). These switches should be tagged: "WARNING. Do not change position of switch except by direction of NAME. . . . . RATE/RANK." Warning tag NAVSHIPS 3950(5-51) may be used for this purpose. In case more than one repair party is engaged in repair work on an electrical circuit, a tag for each party should be placed on the supply switches. After

the work has been completed, each party should remove its own tag but no other.

(2) As a further precaution, metal locking devices are available that can be attached to the switch handles to prevent accidental operation. These locking devices can be obtained through the Ships Parts Segment of the Navy Supply System.

Breaker size	Navy stock no.
50 ampere	H5925-254-4920
100 ampere	H5930-669-7524
225 ampere	H5930-669-7572

All breaker handles are now provided with a 3/32-inch hole permitting fastening the locking device with a standard cotter pin. On earlier breakers it may be necessary to drill a 3/32-inch hole in the handle, using the locking device as a drilling guide. The warning tags can be attached to the eye of the cotter pin.

(3) When checking to see whether circuits are deenergized, never forget to check metering and control circuits as well as power circuits. In many cases metering and control circuits are connected to the supply side of a circuit breaker. A check of power circuits on the load side of a circuit breaker may show that they are dead after the circuit breaker is opened, but such a check gives no assurance whatsoever that associated metering and control circuits are dead. They may or may not be, and MUST be checked to make sure.

(4) No work shall be undertaken on switchboards without first obtaining the approval of the Electrical or Engineer Officer. (See art. 60-37 (10)).

60-37. SAFETY PRECAUTIONS WHEN WORKING ON LIVE CIRCUITS OR EQUIPMENT

When military considerations require that electrical repair or maintenance work be performed, but prohibit deenergizing the circuits involved, extreme measures of precaution must be used. The work should be accomplished only by adequately supervised personnel fully cognizant of the dangers involved. Every care should be taken to insulate the person performing the work from ground and to use all practicable safety measures. The following precautions should be taken when applicable:

(1) Provide ample illumination.

(2) The person doing the work should not wear wrist watch, rings, watch chain, metal articles, or loose clothing which might make accidental contact with live parts or which might accidentally catch and throw some part of his body into contact with live parts. Clothing and shoes should be as dry as possible.

(3) Insulate the worker from ground by means of insulating material covering any adjacent grounded metal with which he might come in contact. Suitable insulating materials are dry wood, rubber mats, dry canvas, dry phenolic material, or even heavy dry paper in several thicknesses. Be sure that any such insulating material is dry, has no holes in it, and no conducting materials embedded in it. Cover sufficient areas so that adequate latitude is permitted for movement by the worker in doing the work.

(4) Cover working metal tools with insulating rubber tape (not friction tape) as far as practicable.

(5) Insofar as practicable, provide insulating barriers between the work and any live metal parts immediately adjacent to the work to be done.

(6) Use only one hand in accomplishing the work, if practicable.

(7) A rubber glove should be used on the hand not used for handling tools. If the work being done permits, rubber gloves should be worn on both hands.

(8) Have men stationed by circuit breakers or switches, and telephone manned if necessary, so that the circuit or switchboard can be deenergized immediately in case of emergency.

(9) A man qualified in first aid for electric shock should be immediately available while the work is being done.

(10) Energized switchboards are a great source of danger. No work shall be undertaken on energized switchboards without first obtaining the approval of the Commanding Officer.

60-38. KEEP COVERS CLOSED

Covers for all fuse boxes, junction boxes, switch boxes, and wiring accessories in general should be habitually kept closed when not required to be open for a specific reason.

60-39. DISCHARGE MACHINES TO GROUND

The electrical charge retained by electrical machinery when secured is, in certain cases, sufficient to cause a severe shock. This must be considered before touching the terminals of an apparently dead machine. Be safe: discharge it to ground by momentarily connecting the terminal to ground using an insulated portable wire or a tool with an insulated handle.

199322

60-40. DISCHARGE CAPACITORS

Capacitors are used in radio interference suppression accessories and for other purposes in electric power and lighting equipment, in interior communication and firecontrol equipment, and in electronics equipment. Prior to touching a capacitor which is connected to a deenergized circuit, or which is disconnected entirely, short circuit the terminals.

60-41. USE OF ALCOHOL

Use of alcohol for cleaning electrical equipment should be avoided and it should never be used on energized equipment or near electrical equipment from which a spark is possible.

60-42. WORKING WITH VOLATILE LIQUIDS

When working with volatile liquids such as insulating varnish, paint, lacquer, turpentine, kerosene, and others from which inflammable vapors may be obtained, they should be considered as dangerous, and ample ventilation to prevent accumulation of fumes provided.

60-43. PRECAUTIONS IN USE OF INFLAMMABLE CLEANING FLUIDS

Gasoline, benzine, ether, and similar inflammable cleaning fluids should never be used on electrical apparatus, even though deenergized. See article 60-413 for the cleaning fluids to be used.

60-44. DEENERGIZING CIRCUITS IN COMPARTMENTS CONTAINING INFLAMMABLE VAPORS

If open-type electrical apparatus is in operation when the presence of explosive vapor is detected, the apparatus should be deenergized by means of switches located outside the contaminated space.

60-45. FIRES

In case of an electrical fire proceed as follows:

(1) Deenergize the circuit or equipment affected and shift the load to stand-by circuits or equipment. In case no stand-by circuit or equipment is available, deenergize the circuit or equipment affected by the fire except in extreme emergency when the need for uninterrupted power is considered to be of such paramount importance as to outweigh the risk incurred by leaving it energized.

(2) Report the fire.

(3) Extinguish the fire with carbon dioxide. Care must be taken to avoid high concentrations of carbon dioxide in confined spaces, as this is dangerous to personnel (See ch. 38). In electrical fires, remember that quick action is most needed for deenergizing the circuit. When this has been done, stop, look, and think, and then act fast to extinguish the fire before it spreads.

ABSTRACT - Prepared to assist the Fireman Apprentice to qualify and to advance to Fireman in the Navy, this training course for enlisted men was developed by the Training Publications Division of the Navy. Chapters are: (1) Preparing for Advancement, (2) Engineering Department, (3) Engineering Fundamentals, (4) Ship Propulsion, (5) Basic Steam Cycle, (6) Boilers, (7) Steam Turbines, (8) Auxiliary Machinery and Equipment, (9) Instruments, (10) Pumps, Valves, and Piping, (11) Shipboard Electrical Equipment, (12) Internal Combustion Engines, and (13) Engineering Watches. Numerous illustrations are provided, and a training film list and glossary are appended. (GB)

BUREAU OF NAVAL PERSONNEL

NAVY TRAINING COURSE NAVPERS 10520-C

PREFACE

This training course has been prepared to assist the Fireman Apprentice to qualify and to advance to Fireman. Study of this training course should be combined with practical experience, with study and review of other applicable Navy Training Courses, and with study of manufacturers' technical manuals, Bureau of Ships Technical Manual, and other applicable material.

As one of the Navy Training Courses, Fireman has been prepared by the Training Publications Division, Naval Personnel Program Support Activity, Washington, D. C., for the Bureau of Naval Personnel. Information provided by numerous manufacturers, publishers, and associations is gratefully acknowledged. Technical assistance has been provided by the Bureau of Ships and the Service School Command, Great Lakes.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

Basic Handtools (Part I, Section 1), NavPers 10085-A

CHAPTER 1

PREPARING FOR ADVANCEMENT

Study of this training course will start you on your way to the time when you will wear a rating badge which will signify that you belong to one of the Engineering and Hull ratings. (See fig. 1-1.) This training course is one of several which will help you meet the technical requirements for advancement.

As a member of the engineering department aboard ship, you know that you are assigned to the heart of the ship. It is through your efforts and the efforts of every other member of the department that your ship becomes alive and is able to meet its commitments anywhere on the oceans of the world.

RATE OF FIREMAN

A Fireman is basically an engineering trainee and must perform a wide variety of tasks. Some of these tasks may seem quite unnecessary and yet there is a very distinct reason for the tasks you will be required to perform. The reason, even though sometimes it may be somewhat obscure, is to increase the operational readiness of the ship and to further your training. Everyday, throughout your Navy career, you will learn something new. This will increase your store of knowledge and thus will make you more valuable to yourself and to the Navy.

You must be able to serve as a competent assistant to the petty officers holding any of the 11 ratings in the engineering department. (These ratings are discussed in chapter 2 of this training course.) You will learn how to operate pumps, motors, and turbines; read gages and thermometers; maintain and clean engines, machinery, and compartments; and identify refrigeration equipment, anchor windlasses, distilling plants, and compressors. You will also stand security and fire watches in engineering spaces, act as a boat engineer, take part in drills, and perform the duties of damage control repair party telephone-talker and messenger.

You may ask yourself the question, "How am I ever going to learn to do all these jobs?" In the beginning, you will work with the petty officer who is responsible for seeing that a specific job is done properly. He will show you exactly how every detail of each operation should be performed. Then he will have you do the job under his supervision. Finally, when he has confidence in you and your ability to do the job, he will give you the opportunity to perform it on your own. This general procedure will be observed throughout your entire period as a striker.

In addition to meeting these requirements, you will also be required to have a basic knowledge of mathematics and blueprint reading. Sources of information which will be useful in learning about these subjects are listed later in this chapter.

ADVANCEMENT AND ELIGIBILITY REQUIREMENTS

Before you can advance in rate, you must fulfill certain military and professional requirements.

Military requirements for advancement are those general qualifications applicable to all enlisted personnel, such as watch standing, first aid, and military conduct. You must show that you are proficient in each of the military qualifications specified for the next higher pay grade. These are discussed in Basic Military Requirements, NavPers 10054-B.

Professional requirements for advancement are technical qualifications that are directly related to the work of each rating.

Both the military requirements and the professional requirements are divided into subject matter groups. These subject matter groups are further subdivided into practical factors and knowledge factors. Practical factors are things that you must be able to do. The knowledge factors are the minimum things you must know in order to perform your duties.

The professional and military requirements just [illegible]d are listed in the Manual of

9338

Qualifications for Advancement in Rating, NavPers 18068 (with changes). This manual provides the minimum requirements for advancement to each pay grade within each rating.

The qualifications for Fireman form the basis for this course, and they were current at the date of this printing. But the qualifications change occasionally, and the questions in the advancement examinations for all pay grades are based on the latest revision. Consequently, long before taking an examination for advancement, you should check for revisions and assure yourself that your knowledge covers all the latest qualifications.

A special form known as the Record of Practical Factors, NavPers 760, is used to keep

Figure 1-1.—Engineering and Hull Ratings. 3.10

9339

9338

a record of your practical factor qualifications. The form lists all practical factors, both military and professional. As you demonstrate your ability to perform each practical factor, appropriate entries are made in the DATE and INITIALS columns by the division officer or your supervising petty officer.

Since changes are made periodically to the Manual of Qualifications for Advancement in Rating, revised forms of NavPers 760 are provided when necessary. Extra space is provided on the Record of Practical Factors for entering additional practical factors as they are published in changes to the Quals Manual. The Record of Practical Factors also provides space for recording demonstrated proficiency in skills which are within the general scope of the rating but which are not identified as minimum qualifications for advancement.

If you are transferred before you qualify in all practical factors, the NavPers 760 form is forwarded with your service record to your next duty station. You can save yourself a lot of trouble by making sure that this form is actually inserted in your service record before you are transferred. If the form is not in your service record, you may be required to start all over again and requalify in the practical factors which have already been checked off.

The Navy has established certain requirements that must be met before you are eligible to take the examination for advancement. You must—

First: Meet basic requirements, such as length of service in pay grade and total service.

Second: Have a statement in your service record that you satisfactorily performed the practical factors for the next higher pay grade.

Third: Have a statement in your service record that you successfully completed the training course for the next higher level of advancement.

Fourth: Be recommended by your commanding officer.

When you satisfy all of these enumerated requirements, you are eligible to participate in the examination. If you pass the examination with a high enough score, your commanding officer has the authority to advance you in rate.

SOURCES OF INFORMATION

The Navy has set definite limits on the material for which you are accountable on the examination. The sources from which examination items are taken are listed in a bibliography called Training Publications for Advancement in Rating, NavPers 10052. This bibliography is available on your ship or station. It is revised annually, so be sure to consult the current edition. It provides the titles of publications and sections of publications that you should study when preparing for the examination. The publications listed contain material covering all the qualifications listed in the Quals Manual. An asterisk (*) identifies the training course or courses that you must complete before you can be eligible to take the examination for advancement.

One of the most useful things you can learn about a subject is how to find out more about it. No single publication can give you all the information you need to know to perform your duties. Basic training courses which will be helpful to you as you prepare for advancement are listed here. Your petty officers will assist you in obtaining other sources of information.

Basic Handtools, NavPers 10085-A
Basic Hydraulics, NavPers 16193
Blueprint Reading and Sketching, NavPers 10077-B
Basic Electricity, NavPers 10086-A
Basic Machines, NavPers 10624-A
Mathematics, Vol. I, NavPers 10069-B

REWARDS OF ADVANCEMENT

Each time you advance, you receive many rewards. These rewards include higher pay and allowances, together with additional pension benefits when you retire. But the really important gains are opportunities for more interesting and challenging assignments, increased respect from your superiors as well as from the men you supervise or help, and the chance for greater fulfillment of your abilities. Above all, you are afforded the opportunity to serve your command, your Navy, and your country at a higher level of responsibility in a more important job.

As a member of the United States Navy, you have the satisfaction of knowing that, as you advance, you are serving your country in a most important way. Do your job well at all times, and take pride in what you do and how you do it. Service to your country is a special privilege. You must make every endeavor to serve with honor.

Tradition, valor, and victory are the Navy's heritage. The long history of outstanding achievements and noble service of the Navy provides an inspiration and a challenge to you and your shipmates. It is up to you to help maintain and enlarge the prestige and the traditions of the naval service.

Page 9340

CHAPTER 2

ENGINEERING DEPARTMENT

The functions of the engineering ratings cover all phases of operation, maintenance, and repair of machinery and equipment under the cognizance (control) of the engineering department. In order to fully understand the nature of your new assignments as a Fireman, you must understand the organization of the engineering department and be familiar with the scope of each Group VII (Engineering and Hull) Rating.

This chapter discusses the administrative and operational functions of the engineering department and the Group VII Ratings.

ORGANIZATION OF ENGINEERING DEPARTMENT

The organization of the engineering department is designed for the efficient operation, maintenance, and repair of the ship's propulsion plant, auxiliary machinery, and piping systems. In addition, the engineering department is responsible for (1) the control of damage, (2) the operation and maintenance of electric generators and distribution systems, (3) repair to the ship's hull, and (4) making general shipboard repairs.

The organization of the engineering department is established by the ship's organization book. This organization is made up of a number of divisions whose functions are discussed later in this chapter.

The organization of the department will vary according to the size of the ship and the engineering plant. Forces afloat, which are primarily concerned with repairs, will have a repair department consisting of many of the engineering ratings, in addition to an engineering department which will be concerned with the operation and maintenance of the propulsion plant of the repair ship or tender. Smaller ships, because of the smaller number of engineering ratings aboard, will combine many ratings into a single division.

Figure 2-1 shows the organization structure of the engineering department aboard a large ship and the functions of the various divisions of the department. Remember that this organization does not represent a particular type or class of ship. It should be noted that the administrative assistant, the department training officer, and the special assistants are aides to the engineer officer and these responsibilities are often assigned as additional duties to officers functioning in other capacities at any of the levels in the direct chain of command.

The three principal assistants to the engineer officer are the main propulsion assistant, the damage control assistant, and the electrical officer. Each of these assistants, in turn, administers those divisions assigned as indicated on the organization chart.

The division officer is responsible for the organization of his division. The Watch, Quarter, and Station Bill reflects the organization of the division by sections and shows the assignments for all emergency drills. The billets assigned depend upon the complement of the division and the capability of personnel assigned to the division.

ENGINEER OFFICER

The head of the engineering department is known as the engineer officer. In addition to the duties of a department head, the engineer officer is responsible for the operation, care, and maintenance of all propulsion and auxiliary machinery; the control of damage; and the accomplishment of repairs within the capacity of the shops in the engineering department.

Detailed information concerning the duties and responsibilities of the engineer officer are given in U. S. Navy Regulations, and in your Ship's Organization and Regulations Manual.

Figure 2-1.—Typical engineering department organization. 27.2

DEPARTMENT ADMINISTRATIVE ASSISTANT

The department administrative assistant functions as an aide to the engineer officer in the details of administration. His responsibilities and duties are as follows:

1. To supervise the operation of the department administrative office, ensuring the maintenance of assigned office spaces and the care and upkeep of office equipment.
2. To train, supervise, and direct the department Yeomen.
3. To screen all incoming correspondence routed to the engineer officer and initiate required action when appropriate; to screen and ensure correct preparation of all outgoing correspondence.
4. To assist in the preparation of all department directives and, following release by the engineer officer, exercise control over their issuance.
5. To supervise the maintenance of department records and maintain a tickler file on all required reports.
6. To coordinate the preparation of the department in-port daily watch bill.
7. To assign tasks to, and evaluate the performance of department Yeoman and other enlisted personnel assigned to the department office.

In an engineering department where an administrative assistant billet is not provided within the framework of the ship's organization, the engineer officer may delegate the duties of such a billet to any competent person.

DEPARTMENT TRAINING OFFICER

The duties of a department training officer are generally performed by the engineer officer, or an assistant to the engineer officer. Some of these duties are:

9342

1. To develop a department training program in support of the training objectives of the ship.

2. To implement approved training plans and policies within the department.

3. To coordinate and assist in the administration of division training programs within the department, including: (1) supervision of the preparation of training materials and review of curricula, training courses, and lesson plans; (2) assistance in the selection and training of instructors; (3) observation of instruction given at drills, on watch, on station, and in the classroom, followed by recommendations to the engineer officer; (4) procurement, through the ship's training officer, of required training aids and devices including films, projectors, training courses, and books.

4. To maintain department training records and training reports.

5. To disseminate information concerning the availability of fleet and service schools.

6. To initiate requisitions for training supplies and materials, subject to the approval of the engineer officer.

MAIN PROPULSION ASSISTANT

The main propulsion assistant is responsible under the engineer officer, for the operation, care, and maintenance of the ship's propulsion machinery and related auxiliaries. He has cognizance over the care, stowage, and use of fuels and lubricating oils. The preparation and care of the Engineering Log and Bell Book are the responsibility of the main propulsion assistant, as is the preparation of operation and maintenance records and procedures.

Machinery Division

If you are assigned to the M division, you will probably work in one of the enginerooms. Normally, there is one engine for each of the ship's propellers. On ships with two or more enginerooms, the enginerooms are generally located immediately aft of the firerooms which supply them with steam. In an emergency, any engineroom can be isolated while the ship continues underway on the remaining engines.

Boiler Division

The B division operates the boilers and the auxiliary fireroom machinery. If you are assigned to this division, your duty station may be one of the firerooms. The firerooms are usually located amidships on the lower levels. There may be as many as 6 or 8 firerooms, depending on the size and type of ship. In ships having more than one fireroom, each fireroom generally has two boilers installed facing each other, or side by side. The boilers are so arranged that any number of them can be used to supply steam to the ship's engines. The firerooms are separated by watertight bulkheads so that any fireroom may be sealed off while the ship operates on the remaining boilers.

On your first trip through the fireroom you may wonder why there are so many lines and valves. You will become familiar with a few of them at a time, and by paying strict attention you will gradually learn how all of them are used.

Steam, water, fuel oil, or air may be carried in these lines. The lines which carry steam or water are covered by insulation and lagging for personnel safety and to prevent heat loss and condensation. Lines are stenciled to indicate the fluid carried and the direction of flow.

These lines do not run through the ship at random, but connect the units of the systems according to a definite plan. In the course of your training you will trace these lines from one unit to another throughout each system. The ship's blueprints and drawings are of particular value in tracing out systems in the engineering plant.

DAMAGE CONTROL ASSISTANT

The damage control assistant is responsible, under the engineer officer, for the prevention and control of damage, including control of stability, list, and trim. Conditions of closure, watertight integrity, and compartment testing are carried out under his supervision. The damage control assistant (DCA) administers the training of the ship's personnel in damage control, firefighting, emergency repair work, and nonmedical defensive measures against NBC warfare. The carpenter shop, shipfitter shop, machine shop, hull shop, and damage control shop are under the cognizance of the DCA. In these shops, all necessary repairs to the hull and the ship's boats, within the shop's capacities are made by the assigned personnel.

Auxiliary Division

Personnel of A division operate the refrigeration plant, air compressors, emergency fire

9343

pumps, emergency diesel generators, and the ventilation and air conditioning systems. They are the boat engineers in small boats and maintain the ship's steering engines. If you are assigned to this division, you may be stationed in the auxiliary spaces or in any other part of the ship where the auxiliaries under A division are located.

The refrigeration plant, similar in many respects to the home refrigerator, preserves the supply of fresh foods and provides ice for general shipboard use. The air compressors supply compressed air for pneumatic tools, for cleaning parts of machinery, for diesel engine air starting systems, and for various other purposes. The equipment assigned to the A division is located throughout the ship.

Repair Division

The R division is responsible for maintaining the watertight integrity of the ship. The R division consists of the shipfitter, carpenter, and damage control shops. If you are assigned to this division you will work in one of these shops.

All damage control and firefighting equipment aboard ship is maintained by the R division. Much of the training of personnel in damage control is carried on by R division personnel.

ELECTRICAL OFFICER

The electrical officer is responsible, under the engineer officer, for the operation, maintenance, and repair of the electrical machinery and systems throughout the ship. The maintenance of the ship's power and lighting systems are the primary concern of the electrical officer. Repair shops are provided on larger ships for extensive repairs to electrical equipment. The IC systems, under the electrical officer, is a part of the E division.

The E division has charge of generators, gyrocompasses, intercommunications, and other electrical equipment. The generators in the enginerooms provide electricity for power and light. The steam turbines which drive the generators are operated by the M division. On electric-drive ships, the E division also operates the main generators and main electric motors which turn the shaft. If assigned to this division, you might work in the main motor rooms, the enginerooms, the electric repair shop, or in the IC rooms.

NBC DEFENSE OFFICER

Since nuclear, biological, and chemical (NBC) warfare defense procedures are classified and subject to frequent modification, it is best to refer to current OpNav Instructions for a detailed description of the NBC defense officer's duties. In general, the NBC defense officer (collateral duty of the damage control assistant) is responsible for the training of shipboard personnel in defense against NBC warfare. He is also responsible for the procurement, distribution, and maintenance of NBC warfare defense equipment. In addition, he must ensure decontamination of personnel, equipment, and the ship; and the management and transportation of NBC casualties with the advice and assistance of the medical officer.

FIRE MARSHAL

The fire marshal, under the engineer officer and the damage control assistant, is responsible for the maintenance and readiness for use of the ship's firefighting equipment. He is also responsible for the prevention and elimination of fire hazards in the ship.

GAS-FREE ENGINEER

The duties and responsibilities of the gas-free engineer are given in chapter 9920(92) of BuShips Technical Manual. Briefly, the gas-free engineer tests and analyzes the air in compartments or voids that have been closed and are being opened for inspection, to determine whether or not such spaces are safe for personnel to enter without danger of poisoning or suffocating. He also determines whether or not it is safe to perform "hot work" (welding or cutting) within, on the exterior boundaries, or in the way of such spaces without danger of fire or explosion. (The person designated as the gas-free engineer must have the qualifications set forth by BuShips.)

DIVISION OFFICERS

In addition to the duties as set forth in U.S. Navy Regulations, the Ship's Organization and Regulations Manual generally prescribes that a division officer shall:

1. Direct the operation of his division through leading petty officers, as prescribed in the division organization.

9344

2. Assign personnel to watches and duties within the division (develop rotation programs for battle stations, watches, and general duties, to ensure the training and proficiency of assigned personnel).

3. Ensure that division personnel receive indoctrination, and military and professional training.

4. Prepare enlisted performance evaluation sheets for personnel of his division.

5. Maintain a division notebook containing personnel data cards, training data, a space and equipment responsibility log, the watch and battle stations to be manned, and such other data as may be useful for the orientation of an officer relieving him, and for ready reference.

6. Be responsible for all forms, reports, and correspondence originated or maintained by his division.

7. Establish and maintain a division organization manual and other directives which may be necessary for the administration of his division.

8. Ensure that prescribed security measures are strictly observed by personnel of his division.

9. Make recommendations for personnel transfers and changes in the division allowance to his department head.

10. Forward requests for leave, liberty, and special privileges, and make recommendations for their disposition.

11. Conduct periodic inspections and exercises, and musters to evaluate the performance and discipline of his division and to initiate disciplinary action, when he deems it necessary, in accordance with the Uniform Code of Military Justice and other regulatory directives.

TECHNICAL ASSISTANTS

The duties of technical assistants (LDO, Warrant Officer, E-8, and E-9 personnel) vary with the different specialties. In general, a technical assistant's duties and responsibilities apply to the operation, maintenance, and repair of machinery, equipment, and systems under the cognizance of the division to which the technical assistant is assigned.

ENLISTED PERSONNEL

In addition to the general ratings for enlisted personnel of the engineering department, there are specific billets or assignments which require special mention. Three of these billets are the oil and water king, the movie operator, and the boat engineer.

Oil and Water King

On a large ship, the billet for oil and water king is usually divided into two billets—one for the fuel oil details, and the other for potable (fresh) water and feed water.

The oil and water king is a Boilerman on steam-driven ships and is generally an Engineman on diesel-driven ships. He has the following responsibilities:

1. Supervising the operation of all valves of the fuel oil system, the transfer and booster pumps, fuel oil manifolds, fuel oil heating coils as necessary, and the fresh water system as prescribed by the casualty control bills for those systems.

2. Properly maintaining fuel oil service tanks, and shifting suction among service tanks.

3. Maintaining the distribution of fuel oil and water so that the ship will remain on an even keel and with proper trim.

4. Preparing fuel and water reports.

139.1

Figure 2-2.—Machinist's Mate recording evaporator readings.

9345

5. Testing and recording the alkalinity, chloride content, hardness, and other properties of feed and boiler water, and making required tests of fuel oil. Detailed information concerning such tests can be obtained from BuShips Technical Manual, chapter 9550 (55) for oil tests and chapter 9560 (56) for water tests.

Movie Operator

Movie operators are generally graduates of a sound motion picture school or duly qualified by competent authority. Provision is generally made to have a sufficient number of operators to accommodate the ship's needs.

Boat Engineer

Firemen, Enginemen, or Machinist's Mates from the A division are detailed as boat engineers. Boat engineers operate, clean, and inspect the parts of the boats assigned to them. Boat engine repairs are undertaken by Enginemen assigned to that duty.

ENGINEERING DEPARTMENT RATINGS

After serving as a Fireman for the required length of time, you may strike for a third class petty officer's rating. But first, you must make an important decision. You may choose any of 11

139.2

Figure 2-3.—Engineman standing watch on a diesel engine.

9346

different ratings. The decision you make will determine largely the kind of work you will be doing throughout the balance of your Navy career.

In general, the engineering department ratings require an aptitude for things mechanical, a degree of proficiency in mathematics and physics, and some experience in repair work. A knowledge of mechanical drawing is also desirable. Navy Training Courses and Correspondence Courses are available, covering many aspects of basic engineering. Self-reliance, ingenuity, and resourcefulness are particularly important to any man striking for an engineering rating.

Schools for engineering ratings are available to those who can qualify. The various types of schools are covered in Basic Military Requirements, NavPers 10054-B. A list of all schools and their requirements is given in the Catalog of U.S. Naval Training Activities and Courses, NavPers 91769 (Revised).

The titles and job descriptions of the various engineering department ratings are given in the sections which follow.

MACHINIST'S MATE (MM)

Machinist's Mates operate and maintain the propulsion turbines, reduction gears, condensers, air ejectors, and such miscellaneous auxiliary equipment in the engineering spaces as pumps, air compressors, generators, evaporators,

Figure 2-4.—Machinery Repairman operating a milling machine. 139.3

9347 9348

valves, oil purifiers, oil and water heaters, governors, and propeller shafts. Figure 2-2 shows a Machinist's Mate recording readings from an evaporator.

Engineman (EN)

Enginemen operate and maintain power plants used to operate shipboard auxiliaries, and to propel boats and ships. In addition to working with internal combustion engines (diesel and gasoline), Enginemen must know how to operate, maintain, and repair many kinds of shipboard auxiliary equipment. Such equipment includes refrigeration and air conditioning systems, pumps, air compressors, and various kinds of hydraulic equipment. Figure 2-3 shows an Engineman standing watch on a diesel engine.

MACHINERY REPAIRMAN (MR)

Machinery Repairmen make all types of machine shop repairs on shipboard machinery. This work requires the skillful use of lathes, milling

Figure 2-5.—A Boilerman removing an atomizer from a burner. 139.4

Figure 2-6.—An Electrician's Mate taking readings on main switchboard. 139.5

9348

machines, boring mills, grinders, power hacksaws, drill presses, and other machine tools, as well as all handtools and measuring instruments usually found in a machine shop. The job of restoring machinery to good working order, ranging as it does from the fabrication of a simple pin or link to the complete rebuilding of an intricate gear system, requires skill of the highest order. Often, in the absence of dimensional drawings or other design information, a Machinery Repairman must depend upon his ingenuity and know-how to successfully machine a repair part. Figure 2-4 shows a Machinery Repairman operating a milling machine.

BOILERMAN (BT)

Boilermen operate all types of marine boilers and fireroom machinery (pumps and forced draft blowers): Boilermen transfer, test, and take soundings of fuel and feed water tanks. Boilermen also maintain and repair boilers, pumps, and associated machinery. Figure 2-5 shows a Boilerman removing an atomizer from a burner.

BOILERMAKER (BR)

Boilermakers test, maintain, and repair marine boilers, heat exchangers, and associated equipment; inspect boilers and effect corrective measures; perform electric arc and oxyacetylene welding in boiler repairs; and maintain records and reports.

ELECTRICIAN'S MATE (EM)

Electrician's Mates stand watch on generators, motors, switchboards, and control equipment; operate searchlights and other electrical equipment; maintain and repair power and lighting circuits, electrical fixtures, motors, generators, distribution switchboards, and other electrical equipment; test for grounds of other casualties; and repair and rebuild electrical equipment in an electrical shop. Figure 2-6 shows an Electrician's Mate taking readings at the main switchboard.

INTERIOR COMMUNICATIONS ELECTRICIAN (IC)

I.C. Electricians maintain and repair interior communications (IC) systems, gyrocompass systems, amplified voice systems, alarm and warning systems, and related equipment; and stand IC and gyrocompass watches. (An I.C. Electrician may be responsible for maintaining motion picture equipment aboard ship.)

139.6

Figure 2-7.—Shipfitter preparing to weld.

SHIPFITTER (SF)

Shipfitters plan, supervise, and perform tasks necessary for fabrication, installation, and repair of metal structures. They install and maintain shipboard and shore base plumbing, and high and low pressure piping systems. Shipfitters organize, supervise, and train personnel in maintenance and repair duties. Figure 2-7 shows a Shipfitter preparing to weld two pieces of angle iron together.

The rating of Shipfitter, established in 1958, replaced the Pipefitter and Metalsmith ratings as follows: one general rating of Shipfitter on the first class and chief levels; two service ratings of Shipfitter P (Pipefitter) and Shipfitter M (Metalsmith) on the third and second class levels. (A general rating reflects the qualification in all aspects of an occupational field and assures a

9349

Figure 2-10.—A Molder finishing a core. 68.124

face
9350

broadly qualified petty officer. A service rating reflects the qualification in some aspects of an occupational field and provides specialization where deemed desirable.)

DAMAGE CONTROLMAN (DC)

Damage Controlmen are qualified in the techniques, skills, and use of equipment of damage control, carpentry, firefighting, and nuclear, biological, and chemical (NBC) warfare defense. Damage Controlmen are responsible for maintaining and repairing damage control equipment and for preserving watertight integrity by such means as adjusting dogs and renewing gaskets on watertight doors, hatches, scuttles, etc. Figure 2-8 shows two Damage Controlmen recharging fire extinguishers.

PATTERNMAKER (PM)

Patternmakers make wooden, plaster, and metal patterns, and other equipment used by Molders in a Navy foundry. They mount patterns on match plates and on follow boards for production molding. Patternmakers make master patterns; make full scale layouts of wooden patterns, core boxes, and templates; and index and store patterns. Figure 2-9 illustrates a Patternmaker sawing a pattern.

MOLDER (ML)

Molders operate foundries aboard ship and at shore stations; make molds and cores, rig flasks, prepare heats, and pour castings of ferrous, nonferrous, and alloy metals; shake out and clean castings; and pour bearings. Figure 2-10 illustrates a Molder finishing a core.

9351

0320

CHAPTER 3

ENGINEERING FUNDAMENTALS

This chapter is designed to acquaint you with various laws and phenomena of nature. Included is information pertaining to matter and energy, force and motion, heat and temperature, pressure, combustion, the laws of perfect gases, and some fundamental information about metals. The information provided here is general in nature; but it has been included to give you a better understanding of how or why engineering machinery operates or produces work. As you study this chapter, remember that anything that occupies space and has weight is called MATTER.

PHYSICS

The forces of physics and the laws of nature are at work in every single piece of machinery or equipment aboard ship. It is by these forces and laws that the machinery and equipment produce work.

MASS, WEIGHT, AND INERTIA

The physical principles of mass and inertia are involved in the design and operation of the heavy flywheels and bull gears that are at work in the ship's engineering plant. The great mass of the wheel tends to keep it rotating once it has been set in motion. The high inertia of the wheel keeps it from responding to small fluctuations in speed and thus helps to keep the engine running smoothly.

The mass and the weight of an object are not the same. The mass of an object is the quantity of matter which the object contains. The weight of the object is equal to the gravitational force with which the object is attracted to the earth. Inertia is that physical property which causes objects that are at rest to remain at rest, unless they are acted upon by some external force; and which causes objects moving at a constant velocity to continue moving at this constant velocity, and in the same direction, until acted upon by some external force.

FORCE

Force is what makes an object start to move, or speed up, or slow down; or keep moving against resistance. This force may be either a push or a pull. You exert a force when you push against a truck, whether you move the truck, or only try to move it. You also exert a force when you pull on a heavy piano, whether you move the piano, or only try to move it. Forces produce or prevent motion, or have a tendency to do so.

A tendency to prevent motion is the frictional resistance offered by an object. This frictional resistance is called frictional force. While it can never cause an object to move, it can check or stop motion. Frictional force wastes power, creates heat, and causes wear. Although frictional force cannot be entirely eliminated, it can be reduced by using lubricants.

SPEED, VELOCITY, AND ACCELERATION

Speed is defined as the distance covered per unit of time. Velocity is speed in a certain direction. Acceleration is the rate at which velocity changes. If, for example, the propeller shaft rate of rotation increases from stop to 100 revolutions per minute (rpm) in 20 minutes, the acceleration is 5 rpm. In other words, the velocity has increased 5 revolutions per minute, during each minute, for a total period of 20 minutes. A body with uniform motion has no acceleration. When the velocity of an object changes by the same amount each second or minute, you have uniform acceleration. Uniform deceleration is obtained when the decrease in velocity is the same each second or minute.

ENERGY

Energy may be described as the ability to do work. In the physical sense, work is done when a force acts on matter and moves it. We use heat energy to turn a steam turbine, and electric energy to drive motors. The mechanical energy

9352

of the pistons in an automobile engine is transmitted to the wheels by the crank shaft, transmission, drive shaft, differential gears, and rear axles. Nuclear energy is used to generate electric power and to drive naval ships.

Perhaps the most common definition of energy is given as "the capacity for doing work." However this is not quite a complete statement because energy can produce other effects which could not be considered as work. For example, heat can flow from one object to another without doing any work; yet heat is a form of energy and the process of heat transfer produces an effect. Therefore, a better definition of energy states that energy is the capacity for producing an effect.

Energy is normally classified according to the size and nature of the objects or particles with which it is associated. So we say that mechanical energy is the energy associated with large objects—usually things that are big enough to see—such as pumps and turbines. Thermal energy is energy associated with molecules. Chemical energy is energy that arises from the forces which bind the atoms together in a molecule. Chemical energy is released whenever combustion or any other chemical reaction takes place. Electrical energy, light waves, and radio waves are examples of energy that are associated with particles smaller than atoms. Nuclear energy is obtained from splitting the atoms. Each of these types of energy (mechanical, thermal, etc.) must also be classified as either (1) stored energy, or (2) energy in transition.

Stored energy is thought of as energy that is actually contained in or stored in an object. There are two kinds of stored energy: potential energy and kinetic energy. Potential energy is energy in an object waiting to be released; while kinetic energy is energy that has been released. For example, potential energy exists in a rock resting on the edge of a cliff, water behind a dam, or steam behind a turbine throttle valve.

Kinetic energy exists because of the velocities of two or more objects. If you push the rock, open the gate of the dam, or open the turbine throttle valve, something will move. The rock will fall, the water will flow, and the steam will jet through the turbine nozzle valves. Thus the potential energy is converted to kinetic energy.

Energy in transition exists when the rock hits the ground, the water hits the bottom of the dam or the paddles of a water wheel, or when the steam hits the blades of the turbine rotor.

In the examples just discussed, an external source of energy was used to get things started. External energy was used to push the rock, open the gate of the dam, or to open the throttle valve. Thus you can see that one energy system affects another energy system. There is a tremendous amount of chemical energy stored in fuel oil; but it will not raise the steam in the boiler until some external energy has been expended to start the oil burning.

Energy can be measured. The most common measurement of expended energy is in work units of foot-pounds. When an object has been moved through a resisting force, work has been done.

WORK

The turbines and other power equipment used aboard ship are important because they do work. WORK is defined as the result of force moving through distance. The unit of measure for work is the FOOT-POUND (ft-lb). The two parts of this unit are the POUND OF FORCE and the FOOT OF DISTANCE.

Force is measured in pounds. The gravitational pull on an object weighing 1 pound is a force of 1 pound. If you lift a 1-pound weight from ground level to a height of 1 foot, you exert a force of 1 pound through a distance of 1 foot—and 1 foot-pound of work is done in the process. A force of 100 pounds is required to raise a 100-pound anvil; if you lift it to the top of a 30-inch bench, the work done is 2 1/2 ft x 100 lb = 250 ft-lb. Work (in foot-pounds), therefore, equals the force (in pounds) times the distance (in feet).

Now suppose you want to move the anvil across the deck without lifting it. It will take a considerable force to slide the anvil—let us say 60 pounds. If you slide it 10 feet, you do 600 foot-pounds of work. Here the force of 60 pounds is required to overcome the resisting force of friction between the anvil and the deck. A great deal of the work done by any machine is the overcoming of the many frictional forces which resist the motion of the parts.

POWER

The ship's main engines are frequently called the POWER PLANT; and they are commonly rated according to how much power they can develop. For example, it might take one man 10 hours to load 20,000 pounds of ammunition on a truck, whereas a crane could do the same job in 5 minutes. The amount of work done is the same, but the crane is much more powerful than

the man. It can do the work faster. POWER, then, relates to work and time. It is the TIME RATE of doing WORK. If we assume that the ammunition is raised an average height of 6 feet, the work done is equal to 6 ft x 20,000 lb or 120,000 ft-lb. Considering the man also as a machine, the power of each of the two machines is found by dividing this amount of work by the time required in each case. Expressing 10 hours in minutes, the man would work at the rate of 120,000 ft-lb ÷ 600 min = 200 ft-lb per min. The computed power of the crane would be 120,000 ft-lb ÷ 5 min = 24,000 ft-lb per min or 400 ft-lb per sec.

The most common unit of power is known as the HORSEPOWER. One horsepower is equivalent to 550 ft-lb per second, or 33,000 ft-lb per minute. Thus, if a lifting machine raises a weight of 100 pounds at the rate of 250 ft-lb per second, the machine is exerting only 0.454 of a horsepower (250 ft-lb ÷ 550 ft-lb = 0.454 hp).

If a crane hoists 2,000 pounds of cargo to a height of 30 feet in 5 seconds, how much horsepower is developed? Here is how to get the answer:

$$\text{Power} = \frac{\text{work}}{\text{time}} = \frac{2{,}000 \text{ lb} \times 30 \text{ ft}}{5 \text{ sec}}$$

$$= 12{,}000 \text{ ft-lb per sec}$$

$$\text{Horsepower} = \frac{12{,}000 \text{ ft-lb per sec}}{550 \text{ ft-lb per sec}} = 21.8$$

Or suppose a turbine has a known horsepower of 37,500 at rated capacity, and you want to know how much work it does. You find out by multiplying the developed horsepower by the hours in operation. This gives HORSEPOWER-HOURS, which is a measure of work for main propulsion machinery.

LAWS OF GASES

The energy transformation of major interest in the shipboard engineering plant is the transformation from heat to work. To see how this transformation occurs, we need to consider the pressure, temperature, and volume relationships which hold true for gases. In the middle of the 17th century, an English scientist, Robert Boyle, made some interesting discoveries concerning the relationship between the pressure, the temperature, and the volume of gases. In 1787, Jacques Charles, a Frenchman, proved that all gases expand the same amount when heated one degree if the pressure is kept constant. The relationships that these two men discovered are summarized as follows:

1. When the temperature is held constant, increasing the pressure on a gas causes a proportional decrease in volume. Decreasing the pressure causes a proportional increase in volume.

2. When the pressure is held constant, increasing the temperature of a gas causes a proportional increase in volume. Decreasing the temperature causes a proportional decrease in volume.

3. When the volume is held constant, increasing the temperature of a gas causes a proportional increase in pressure. Decreasing the temperature causes a proportional decrease in pressure.

Suppose we have a boiler in which steam has just begun to form. With the steam stop valves still closed, the volume of the steam remains constant while the pressure and the temperature are both increasing. When operating pressure is reached, and the steam stop valves are opened, the high pressure of the steam causes the steam to flow to the turbines. The pressure of the steam thus provides the potential for doing work; the actual conversion of heat to work is done in the turbines.

PRESSURE AND VACUUM

Because pressure is very important to the engineering plant, it is necessary that you understand the relationships between gage pressure, atmospheric pressure, vacuum, and absolute pressure. These relationships are indicated in figure 3-1.

Gage Pressure

Gage pressure is the pressure actually shown on the dial of a gage which registers pressures at or above atmospheric pressure. Gage pressure is usually shown in pounds per square inch (psi); but it may be shown in inches of water, mercury, or other liquid. A reading of 1 inch of water means that the exerted pressure is able to support a column of water 1 inch high, or that a column of water in a U-tube would be displaced 1 inch by the pressure being measured. Similarly, a gage pressure reading of 12 inches of mercury means that the measured pressure is able to support a column of mercury 12 inches high. Gages are calibrated in inches of water

9354

139.8

Figure 3-1.—Relationships between vacuum, gage pressure, absolute pressure, and atmospheric pressure.

when they are to be used for the measurement of very low pressures. Inches of mercury may be used when the range of pressures to be measured is somewhat higher, since mercury is about 14 times as heavy as water.

Note that a gage pressure reading of zero means that the pressure being measured is exactly the same as the existing atmospheric pressure. A gage reading of 50 psi means that the pressure being measured is 50 psi IN EXCESS OF the existing atmospheric pressure.

Atmospheric Pressure

Atmospheric pressure, or the pressure exerted by the weight of the air in the atmosphere, is measured with a BAROMETER (fig. 3-2). A barometer is similar to a manometer (see chapter 9), except that the indicating tube is sealed at the top. A barometer may be made by filling a tube with mercury and then inverting it so that the open end rests in a container of mercury which is open to the atmosphere. The absence of pressure at the closed end of the tube permits atmospheric pressure, acting upon the surface of the mercury in the open container, to hold the mercury in the tube at a height which corresponds to the pressure being exerted.

Normally, at sea level, atmospheric pressure will hold the column of mercury at a height of approximately 30 inches. Since a column of mercury 1 inch high exerts a pressure of 0.49 pounds per square inch, a 30-inch column of mercury exerts a pressure which is equal to (30 x 0.49) 14.7 pounds per square inch. Thus we can say that atmospheric pressure (zero gage pressure) at sea level is 14.7 psi, or 14.7 pounds per square inch absolute (psia). Notice, however, that this figure of 14.7 psi is the STANDARD for atmospheric pressure. Since fluctuations from this standard are shown on the barometer, the term BAROMETRIC PRESSURE is used to describe the atmospheric pressure which exists at any given moment. As a rule, you can use the term ATMOSPHERIC PRESSURE and the value 14.7 psi in place of the actual barometric pressure; but there may be times when it will be important to know the ACTUAL (barometric) pressure, in order to make precise measurements of gage pressure or vacuum.

Vacuum

A space in which the pressure is LESS than atmospheric pressure is said to be under VACUUM. The amount of vacuum is expressed in terms of the difference between the pressure in the space and the existing atmospheric pressure. Vacuum is measured in inches of mercury—that is, the number of inches a column of mercury in a U-tube would be displaced by a pressure equal to the DIFFERENCE between the pressure in the vacuum space and the existing atmospheric pressure.

Vacuum gage scales are marked from 0 to 30. When a vacuum gage reads zero, the pressure in the space is the same as the existing atmospheric pressure—or, in other words, there is no vacuum. A vacuum gage reading of 30 inches of mercury would indicate a nearly perfect vacuum. In actual practice, it is impossible to obtain a perfect vacuum; and the highest vacuum gage readings are seldom over 29 inches of mercury.

Absolute Pressure

Absolute pressure is atmospheric pressure PLUS gage pressure, or atmospheric pressure MINUS vacuum. For example, if gage pressure is 300 psi, absolute pressure is 314.7 psi; or if the measured vacuum is 10 inches of mercury, absolute pressure is approximately 20 inches of mercury. It is important to note that the amount of PRESSURE in a space under vacuum can be expressed only in terms of absolute pressure.

Sometimes it is necessary to convert a reading from inches of mercury to pounds per square inch. Figure 3-1 gives you all the information you need to make this conversion. Since atmospheric pressure is equal to 14.7 psi or to 30 inches of mercury, it is easy to see that 1 inch

9355

correct the reading, you must ADD the weight of the column of water—that is, you must add 0.433 psi to the gage reading for each foot of rise.

For example, assume that a water pressure gage is connected 5 feet ABOVE the point at which the pressure is being measured. The gage reading is 30 psi. To obtain the actual pressure at the point of measurement, you must add (5 x 0.433 psi) 2.17 psi to the gage reading. Thus the actual pressure is 32.17 psi.

PRINCIPLES OF HYDRAULICS

The word hydraulics is derived from the Greek word for water (hydōr) plus the Greek word for flute (aulos). The term "hydraulics" originally covered a study of the physical behavior of water at rest and in motion. However, the meaning of the term "hydraulics" has been broadened to cover the physical behavior of all liquids, including the oils that are used in present day hydraulic systems.

During the period before World War I, the Navy began to apply hydraulics extensively to naval mechanisms. Since that time, naval applications have increased to the point where many ingenious hydraulic devices are used in the solution of problems of gunnery, navigation, and aeronautics. Aboard ship today the applications of hydraulics include anchor windlasses, power cranes, steering gear, remote controls, power drives for the elevating of guns and training of mounts and turrets, powder and projectile hoists, recoil systems, gun rammers, and airplane catapults.

The foundations of modern hydraulics began in 1653 when Pascal discovered that "pressure set up in a liquid acts equally in all directions." This pressure acts at right angles to the containing surfaces.

In figure 3-3 if the liquid standing on a square inch (A) at the bottom of the tank weighs 8 pounds, a pressure of 8 pounds is exerted in every direction at A. The liquid resting on A will push equally downward and outward. But the liquid on every other square inch of the bottom surface is also pushing downward and outward in the same manner.

When we apply a force to the end of a column of confined liquid, the force is transmitted not only straight through to the other end, but also equally in every direction throughout the column—forwards, backwards, and sideways—so that the containing vessel is literally filled with pressure. This is the reason that a flat fire hose takes on

5.70

Figure 3-3.—Illustration showing principle of Pascal's law.

a circular cross-section when it is filled with water under pressure. The outward push of the water is equal in every direction. Water will leave the hose at the same velocity, through leaks, regardless of where the leaks are in the hose.

Let us now consider the effect of Pascal's law in the system shown in figure 3-4. If the force at piston A is 100 pounds and the area of the piston is 10 square inches, then the pressure in the liquid must be 10 pounds per square inch (psi). This pressure is transmitted to piston B—so that for every square inch of its area, piston B will be pushed upward with a force of 10 pounds. In this example we are merely considering a liquid column of equal cross-section so that the areas of the pistons are equal. All we have done is to carry a 100-pound force around a bend; however, the principle illustrated is the basis for practically all mechanical hydraulics.

The same principle may be applied where the input piston is much smaller than the output piston or vice versa. Assume that the area of the input piston is 2 square inches and the area of the output piston is 20 square inches. If you

9357

apply a pressure of 20 pounds to the smaller piston, the pressure created in the liquid will again be 10 pounds per square inch because the force is concentrated on a smaller area. The upward force on the larger piston will be 200 pounds—10 pounds for each of its 20 square inches. Thus you can see if two pistons are used in a hydraulic system, the force acting on each piston will be directly proportional to its area, and the magnitude of each force will be the product of the pressure and the area of the piston.

PRINCIPLES OF PNEUMATICS

Pneumatics is that branch of mechanics that deals with the mechanical properties of gases. Perhaps the most common application of these properties, used in the Navy today, is the use of compressed air. Compressed air is used to transmit pressure, according to Pascal's principle, in a variety of applications. For example, in tires and air cushioned springs, compressed air acts as a cushion to absorb shock. Air brakes on locomotives and large trucks contribute greatly to the safety of railroad and truck transportation. In the Navy, compressed air is used in numerous ways. For example, tools such as riveting hammers and pneumatic drills are air operated. Automatic combustion control systems utilize compressed air for the operation of the instruments. Compressed air is also used in diving bells and diving suits. Perhaps a brief discussion on the use of compressed air as an aid in the control of submarines will best explain the theory of pneumatics.

Submarines are designed with a number of tanks that may be used for the control of the ship. These tanks may be flooded with water to submerge; or they may be filled with compressed air to surface.

The compressed air for the pneumatic system is maintained in storage tanks (called banks) at a pressure of 4,500 psi. When surfacing, the pneumatic system delivers compressed air to the desired control tanks. Since the pressure of the air is greater than the pressure of the water, the water is forced out of the tank. As a result, the weight of the ship is decreased; it becomes more buoyant, and thus it will tend to rise to the surface.

HEAT

You undoubtedly know from experience that heat and temperature are related; however, they are not the same. Water from a water main feels cool until it has been over a fire a few minutes. It evidently must have received something from the fire. If you place two pennies together, one of which was heated by being held in the flame of a match, in a short time the two pennies will be equally warm. Again something passed into the cooler object and made it hot. That something is called heat.

Many forms of mechanical action also produce considerable quantities of heat. For example, you rub your hands together to warm them when they are cold. Matches are ignited by rubbing them on a rough surface. A Shipfitter can notice heat in a piece of metal after hammering it; and the head of a nail is heated when the nail is driven into wood.

The molecules in the nail (as in all matter) are in continual motion. The blow on the nail increases the molecular motion. The molecules in the top layer receive the impulse from the hammer, and vibrate with greater violence. The increased vibration and energy of motion is passed on to layer after layer of molecules. Thus the effect of the blow is to produce a general increase in the motion of the molecules. This energy of molecular motion is called heat.

Because molecules are constantly in motion, they exert a pressure on the walls of the pipe, boiler, cylinder, or other object in which they are contained. Also, the temperature of any substance arises from and is directly proportional to the activity of the molecules. Therefore, every time you read thermometers and pressure gages you are finding out something about the amount of internal energy contained in the substance. High pressures and temperatures indicate that the molecules are moving rapidly and that the substance therefore has a lot of internal energy.

HEAT is a more familiar term than internal energy, yet one that may actually be more difficult to define correctly. The important thing to remember is that heat is THERMAL ENERGY IN TRANSITION—that is, it is thermal energy that is moving from one substance or system to another.

An example will help to illustrate the difference between heat and internal energy. Suppose there are two equal lengths of pipe, made of identical materials and containing steam at the same pressure and temperature. One pipe is well insulated, the other is not insulated at all. From everyday experience you know that more heat will flow from the uninsulated pipe than from the insulated pipe. When the two pipes are first filled with steam, the steam in one pipe contains exactly as much internal energy as the steam in the other

9358

Figure 3-4.—Principle of mechanical hydraulics. 5.181

pipe. We know this is true because the two pipes contain equal volumes of steam at the same pressure and at the same temperature. After a few minutes, the steam in the uninsulated pipe will contain much less internal energy than the steam in the insulated pipe, as we can tell by measuring the pressure and the temperature of the steam in each pipe. What has happened? Stored thermal energy—internal energy—has moved from one place to another, first from the steam to the pipe, then from the uninsulated pipe to the air. The MOVEMENT or FLOW of thermal energy is what should be called heat.

Units of Measurement

Both internal energy and heat are usually measured using the unit called the BRITISH THERMAL UNIT (Btu). For most practical engineering purposes, 1 Btu is defined as the amount of thermal energy required to raise the temperature of 1 pound of water through 1°F.

When large amounts of thermal energy are involved, it is usually more convenient to use multiples of the Btu. For example, 1 kB is equal to 1,000 Btu, and 1 mB is equal to 1,000,000 Btu.

Another unit in which thermal energy may be measured is the CALORIE, the amount of heat required to raise the temperature of 1 gram of water 1°C. One Btu equals 252 calories.

Sensible Heat and Latent Heat

The terms SENSIBLE HEAT and LATENT HEAT are often used to indicate the effect that the flow of heat has on a substance. The flow of heat from one substance to another is normally reflected in a temperature change in each substance—the hotter substance becomes cooler, the cooler substance becomes hotter. However, the flow of heat is NOT reflected in a temperature change in a substance which is in the process of changing from one physical state (solid, liquid, or gas) to another. When the flow of heat is reflected in a temperature change, we say that SENSIBLE HEAT has been added to or removed from the substance. When the flow of heat is NOT reflected in a temperature change but IS reflected in the changing physical state of s substance, we say that LATENT HEAT has been added or removed.

Does anything bother you in this last paragraph? It should. Here we are, talking about adding and removing heat. And, furthermore, we are talking about sensible heat and latent heat as though we had two different kinds of heat to consider. As noted before, this is common (if inaccurate) engineering language. So keep the following points clearly in mind: (1) heat is the flow of thermal energy; (2) when we talk about adding and removing heat, we mean that we are providing temperature differentials so that thermal energy can flow from one substance to another; and (3) when we talk about sensible heat and latent heat, we are talking about two different kinds of EFFECTS that can be produced by heat, but not about two different kinds of heat.

The three basic physical states of all matter are SOLID, LIQUID, and GAS (or vapor). The physical state of a substance is closely related

9359 9328

to the distance between molecules. As a general rule, the molecules are closest together in solids, farther apart in liquids, and farthest apart in gases. When the flow of heat to a substance is not reflected in a temperature change, we know that the energy is being used to increase the distance between the molecules of the substance and thus to change it from a solid to a liquid or from a liquid to a gas. You might say that latent heat is the energy price that must be paid for a change of state from solid to liquid or from liquid to gas. The energy is not lost; rather, it is stored in the substance as internal energy. The energy price is "repaid," so to speak, when the substance changes back from gas to liquid or from liquid to solid, since heat flows FROM the substance during these changes of state.

Figure 3-5 shows the relationship between sensible heat and latent heat for one substance, water, at atmospheric pressure. (The same kind of chart could be drawn up for other substances; however, different amounts of thermal energy would be involved in the changes of state.)

If we start with 1 pound of ice at 0°F, we must add 16 Btu in order to raise the temperature of the ice to 32°F. We call this adding SENSIBLE HEAT. To change the pound of ice at 32°F to a pound of water at 32°F, we must add 144 Btu (the LATENT HEAT OF FUSION). There will be no change in temperature while the ice is melting. After all the ice has melted, however, the temperature of the water will be raised as additional heat is supplied. If we add 180 Btu—that is, 1 Btu for each degree of temperature between 32°F and 212°F—the temperature of the water will be raised to the boiling point. To change the pound of water at 212°F to a pound of steam at 212°F, we must add 970 Btu (the LATENT HEAT OF VAPORIZATION). After all the water has been converted to steam, the addition of more heat will cause an increase in the temperature of the steam. If we add about 44 Btu to the pound of steam which is at 210°F, we can superheat it to 300°F.

The same relationships apply when heat is being removed. The removal of 44 Btu from the pound of steam which is at 300°F will cause the temperature to drop to 212°F. As the pound of steam at 212°F changes to a pound of water at 212°F, 970 Btu are given off. When a substance is changing from a gas or vapor to a liquid, we usually use the term LATENT HEAT OF CONDENSATION for the heat that is given off. Notice, however, that the latent heat of condensation is exactly the same as the latent heat of vaporization. The removal of another 180 Btu of sensible heat will lower the temperature of the pound of water from 212° F to 32° F. As the pound of water at 32° F changes to a pound of ice at 32° F, 144 Btu are given off without any accompanying change in temperature. Further removal of heat causes the temperature of the ice to decrease.

TEMPERATURE

The temperature of an object is a measure of how hot or cold the object is; and it can be measured by thermometers and read on their temperature scales.

The TEMPERATURE SCALES employed to measure temperature are the Fahrenheit scale and the centigrade scale. In engineering and for practically all purposes in the Navy, the Fahrenheit scale is used. It may, however, be necessary for you to convert centigrade readings to the Fahrenheit scale, so both scales are explained here.

The FAHRENHEIT SCALE has two main reference points—the boiling point of pure water at 212°, and the freezing point of pure water at 32°. The size of the Fahrenheit degree is 1/180 of the total temperature change from 32° to 212°. And the scale can be extended in either direction—to higher temperatures without any limits, and (by using MINUS degrees) to lower temperatures down to the lowest temperature theoretically possible, the so-called ABSOLUTE ZERO. This temperature is -460°, or 492° below the freezing point of water.

In the CENTIGRADE SCALE, the freezing point of pure water is 0° and the boiling point of pure water is 100°. Therefore, 0°C and 100°C are equivalent to 32°F and 212°F, respectively. Each centrigrade degree is larger than a Fahrenheit degree (since there are only 100 centigrade degrees between the freezing and boiling points of water, while this same temperature change requires 180 degrees in the Fahrenheit scale). Therefore the centrigrade degree is 180/100 or 1.8 Fahrenheit degrees. In the centrigrade scale absolute zero is -273°.

Figure 3-6 shows the two temperature scales in comparison. This figure also introduces the simplest of the temperature measuring instruments, the liquid-in-glass THERMOMETER. The two thermometers shown are exactly alike in SIZE and SHAPE, the only difference being in the outside markings or SCALES on them. Each thermometer is a hollow glass tube which has a mercury-filled bulb at the bottom, and which is sealed at the top. Mercury, like any liquid, expands on being heated, and it will rise in the

9360

Figure 3-5.—Relationship between sensible heat and latent heat for water at atmospheric pressure.

hollow tube. The illustration shows the Fahrenheit thermometer with its bulb standing in ice water (32°F), while the centigrade thermometer is in boiling water (100°C).

The essential point to remember is that the level of the mercury in a thermometer depends only on the temperature to which the bulb is exposed. If you were to exchange the thermometers, the mercury in the centigrade thermometer would drop to the level at which the mercury now stands in the Fahrenheit thermometer, while the mercury in the Fahrenheit thermometer would rise to the level at which the mercury now stands in the centigrade thermometer. The temperatures would be 0°C for the ice water and 212°F for the boiling water.

If you place both thermometers in water containing lumps of ice, the Fahrenheit thermometer will read 32° and the centigrade thermometer will read 0°. Heat the water slowly. The temperature will not change until the ice in the water has completely melted (a great deal of heat is required just to melt the ice), then both mercury columns will begin to rise. When the mercury level is at the +10° mark in the centigrade thermometer, it will be at the +50° mark in the Fahrenheit thermometer. The two columns will rise together at the same speed, and when the water finally boils they will stand at 100°C and 212°F, respectively. The same temperature change—that is, the same amount of heat transferred to the water—has raised the temperature 100

9361

0320

Figure 3-6.—Temperature scales: A. Fahrenheit scale. B. Centrigrade scale.

centigrade degrees and 180 Fahrenheit degrees, but the actual change in heat energy is EXACTLY THE SAME.

COMBUSTION

The term "combustion" refers to the rapid chemical union of oxygen with the fuel. The perfect combustion of fuel should result in carbon dioxide, nitrogen, water vapor, and sulphur dioxide. The oxygen furnished to the fuel, in order to burn it, is obtained from the air. Air is a mechanical mixture containing by weight 23.15 percent oxygen and 76.85 percent nitrogen. The oxygen only is used in combustion of the fuel; the nitrogen, being an inert gas, has no chemical effect upon the combustion.

The chemical combination obtained during combustion results in the liberation of heat energy, a portion of which is used to propel the ship. Actually, what happens is a rearrangement of the atoms of the chemical elements into new combinations of molecules. In other words, as the temperature of the fuel oil in the presence of oxygen is increased to the ignition point, the various chemical elements in the fuel begin to separate from each other and unite with certain amounts of oxygen, to form entirely new substances, which give off heat energy in the process. A good fuel has a high speed of combustion, thus producing a large amount of heat in a short time.

PERFECT COMBUSTION cannot as yet be achieved in either a boiler or the cylinders of an internal combustion engine, but this is the objective. Theoretically, it is simple. It consists of bringing each particle of the fuel (heated to its ignition temperature) into contact with the correct amount of oxygen. The following factors are involved:

1. Sufficient air must be supplied.
2. The air and fuel particles must be thoroughly mixed.
3. Temperatures must be high enough to maintain combustion.
4. Enough time must be allowed to permit completion of the process.

What is known as COMPLETE COMBUSTION, however, can be achieved. This is accomplished by supplying more oxygen to the process than would be required if perfect combustion were possible. The result is that some of the excess oxygen appears in the combustion gases.

STEAM

Steam is water to which enough heat has been added to convert it from the liquid to the gaseous state. When heat is added to water in an open container, steam forms, but it quickly mixes with air and cools back to water that is dispersed in the air, making the air more humid. If you add the heat to water in a closed container, the steam builds up pressure. If you add exactly enough heat to convert all the water to steam at the temperature of boiling water, you get saturated steam. SATURATED STEAM is steam saturated with all the heat it can hold at the boiling temperature of water.

The boiling temperature of water becomes higher as the pressure over the water becomes higher. Steam hotter than the boiling temperature of water is called SUPERHEATED STEAM. When steam has 250°F of superheat,

0362

the actual temperature is the boiling temperature plus 250°F. At 600 psi the boiling temperature of water is 489°F. So if steam at 600 psi has 250°F of superheat, its actual temperature is 739°F. WET STEAM is steam at the boiling temperature, but still containing some water particles. DESUPERHEATED STEAM is steam which has been cooled by being passed through a pipe extending through the steam drum; in the process the steam loses all but about 20° or 30° of its superheat. The advantage of desuperheated steam is that it is certain to be dry, and yet it is not so hot that special alloy steels would be required for the construction of the piping that carries the desuperheated steam about the ship.

METALS

As you look around, you can see that not only is your ship constructed of metal, but that the boilers, piping system, machinery, and even your bunk and locker are constructed of some type of metal. No one type of metal can serve all the needs aboard ship, so many types of metals or metal alloys must be used. For some parts of a ship a strong metal must be used and on other parts a lightweight metal is needed. Some areas require special metal that can be shaped or worked very easily.

The physical properties of some metals or metal alloys make them more suitable for one use than for another. Various terms are used in describing the physical properties of metals. By studying the following explanations of these terms you should have a better understanding of why certain metals are used on one part of the ship's structure and not on another part.

STRENGTH refers to the ability of a metal to maintain heavy loads (or force) without breaking. Steel, for example, is strong, but lead is weak.

HARDNESS refers to the ability of a metal to resist penetration, wear, or cutting action.

MALLEABILITY is a property of a metal that allows it to be rolled, forged, hammered, or shaped, without cracking or breaking. Copper is a very malleable metal.

BRITTLENESS—any metal that will shatter easily is brittle. Metals such as cast iron or cast aluminum, and some very hard steels are brittle.

DUCTILITY refers to the ability of a metal to stretch or bend without breaking. Soft iron, soft steel, and copper are ductile metals.

TOUGHNESS—metal that will not tear or shear (cut) easily and that will stretch without breaking has the property of toughness.

Metal preservation aboard ship is a continuous operation since the metals are constantly exposed to fumes, water, acids, and moist salt air; all of these will eventually cause corrosion. The corrosion of iron and steel is called rusting and results in the formation of iron oxide (iron and oxygen) on the surface of the metal. Iron oxide (or rust) can be easily identified by its reddish color. (A blackish hue occurs in the first stage of rusting, but is seldom thought of as rust.) Corrosion can be reduced, or prevented, by using better grades of base metals, by adding special metals such as nickel and chromium, or by coating the surface with paint or other metal preservatives.

Metals and alloys are divided into two general classes: ferrous and nonferrous. Ferrous metals are those that are composed primarily of iron. Nonferrous metals are those that are composed primarily of some element or elements other than iron. One way to tell a common ferrous metal from a nonferrous metal, is by using a magnet; most ferrous metal is magnetic and nonferrous metal is nonmagnetic.

To obtain the desired physical properties of a metal, elements must be alloyed (or mixed) together. For example, by alloying (or mixing) chromium and nickel with iron, a metal known as special treated steel is produced. Special treated steel (STS) has great resistance to penetrating and shearing forces and is used for gun shields, turrets, protective decks, and other vital areas. A nonferrous alloy that has many uses aboard ship is copper-nickel, which is used extensively in salt water piping systems. Copper-nickel is produced by mixing copper and nickel together. There are many other different metals and alloys used aboard ship that will not be discussed here.

With all the different types of metals used aboard ship, some way of identifying these metals in the storeroom must be used. At the present time the Navy utilizes two systems of identifying metals: the continuous identification marking system and the color marking system. These systems have been designed so that even after a portion of the metal has been removed, the identifying marks are still visible.

In the continuous identification marking system, the identifying information is actually painted on the metal with a heavy ink. This marking appears at specified intervals over the length of the metal. The marking contains the producer's trademark and the commercial designation of the metal. The marking also indicates the physical

condition of the metal such as "cold drawn," "cold rolled," "seamless," and others.

In the color marking system, a series of color symbols with a related color code is used to identify metals. The term "color symbol" refers to a color marking actually painted on the metal. The symbol is composed of one, two, or three colors and is painted on the metal in a conspicuous place. These color symbols correspond to the elements of which the metal is composed.

For further information on the metals used aboard ship, the properties of these metals, and the identification systems used, refer to the Navy Training Course Shipfitter 3 & 2, NavPers 10595-A.

9364

CHAPTER 4

SHIP PROPULSION

The primary function of any marine engineering plant is to convert the chemical energy of a fuel into useful work, and to utilize that work in the propulsion of the ship. A propulsion unit consists of the machinery and equipment, including their controls, that are mechanically, electrically, or hydraulically connected to a propulsion shaft.

This chapter contains information on the principles of ship propulsion, and in addition acquaints you with some of the different types of ship propulsion units, which include the geared-turbine drive, the turbine electric drive, diesel electric (d-c) drive and the straight diesel engine drive.

PRINCIPLES OF SHIP PROPULSION

A ship is propelled through the water by means of some device which imparts velocity to a column of water and moves it in the direction opposite to the direction in which it is desired to move the ship. A reactive force (thrust) is thereby developed against the velocity-imparting device, and this thrust, when transmitted to the ship, causes the ship to move through the water. All propelling devices—oars, paddle wheels, and propellers—are designed to move a column of water in order to build up a reactive force sufficient to move the ship.

The screw-type propeller is the propulsion device used on practically all naval ships. The thrust developed on the propeller is transmitted to the ship's structure by the shaft through the thrust bearing. On most steam-driven ships, the mechanical energy required to turn the propeller is provided by the turbines. Reduction gears are used on practically all steam-driven ships to connect the turbine to the shaft in a manner that allows the turbines to operate at high rotational speeds while the propellers operate at lower rotational speeds, thus allowing most efficient operation of both turbines and propellers.

The general principle of ship propulsion is illustrated in figure 4-1.

TYPICAL PROPULSION UNITS

Propulsion units with various types and designs of prime movers are currently in use in naval ships. The prime movers of a propulsion unit may be a geared turbine, turbine and a

Figure 4-1.—Principle of ship propulsion.

9365

ease

Figure 4-2.—Geared-turbine propulsion unit. 47.1

generator, a diesel engine and a generator, or a straight diesel engine. These are the most common types of prime movers of propulsion units and the ones with which we are most concerned.

GEARED-TURBINE DRIVE

In the geared-turbine drive, the unit parts or sections which make up the individual propulsion units consist of the main turbines and the reduction gear.

Figure 4-2 shows the general arrangement of the turbines and gears in a geared-turbine propulsion unit. Not all geared turbine plants have the cruising turbine which is included in the diagram. Ordinarily, cruising turbines will be found in only the older destroyers.

In a typical destroyer propulsion plant, the speed reduction ratio between the cruising turbine shaft and high pressure turbine shaft is approximately 1.8 to 1. The speed ratio between the high pressure turbine shaft and propeller shaft is 16 to 1, and the ratio between the low pressure turbine and propeller shaft is 13 to 1. In other words, in operation, if the propeller shaft is revolving at 100 rpm, the cruising turbine will be revolving at 2,880 rpm (1.8 x 16 x 100), the high pressure turbine at 1,600 rpm (16 x 100), and the low pressure turbine at 1,300 rpm (13 x 100).

Figure 4-2 shows two astern elements, one at each end of the low pressure turbine. This arrangement is typical for combatant type ships; auxiliary type ships usually have one astern element instead of two, and that one invariably is located at the forward end of the low pressure turbine (the end farthest from the reduction gear).

THE PROPULSION SHAFT, which extends from the main gear (low speed) shaft of the reduction gear to the propeller, is supported and held in alignment by the SPRING BEARINGS, the STERN TUBE BEARINGS, and the STRUT BEARING. The axial thrust, acting on the propulsion shaft as a result of the pushing effect of the propeller, is absorbed in the MAIN THRUST BEARING. In most ships, the main thrust bearing is located at the forward end of the main shaft, within the reduction gear casing. In some very large ships, however, the main shaft thrust bearing is located farther aft in a machinery space or a shaft alley.

TURBINE ELECTRIC DRIVE

Turbine electric drive installations have a single turbine unit for each installed shaft. Figure 4-3 shows the diagrammatic arrangement of a turbine electric propulsion unit. As you can see, the propulsion unit includes a turbine, main generator, propulsion motor, and a propulsion control board, a direct current generator for supplying rotor field current to the propulsion

9366 7356

Figure 4-3.—Diagram of the turbo-electric drive. 47.2

motor and excitation current to the generator. Figure 4-4 is an illustration of a typical control board.

The speed reduction ratio between turbine and propeller in the turbo-electric drive is approximately the same as in the geared-turbine drive and is brought about electrically. For example, in one class of turbo-electric drive type destroyer escort, the normal operating range fixed speed ratio between the turbine-generator set and the propulsion motor is 14 to 1.

One of the outstanding differences between geared drive and electric drive is that the latter does not have an astern turbine element. In the electric drive, the direction of rotation of the propulsion motor, and consequently the propeller, is controlled by the electrical switch setup. Therefore, there is no need to reverse turbine rotation for astern operation.

DIESEL (D-C) ELECTRIC DRIVE

Diesel d-c electric drive is best suited to ships in the low or medium horsepower range up to about 6,000 shaft horsepower. It has been installed in approximately 175 escort ships and 500 surface ships and craft of other types, including minesweepers, submarine tenders, older submarines, fleet and harbor tugs, fuel oil tankers and barges, rescue and salvage craft and miscellaneous unclassified craft.

Figure 4-5 shows one of the main propulsion diesel engines aboard an oceanographic research ship. Figure 4-6 shows the main propulsion switchboard operating station aboard the same ship.

The propulsion equipment for a fleet tug that utilizes diesel d-c drive consists of four diesel-engine d-c generators furnishing power to one propulsion motor rated at 3,000 horsepower

which, in turn drives the propeller. The four generating units are normally located amidships—two on the port side and two on the starboard side.

The control of direction (forward or reverse) and the speed of propeller rotation is accomplished at the control board. A typical control board installation aboard a fleet tug is shown in figure 4-7.

In the propulsion plants of some diesel-driven ships, there is no mechanical connection between the engine(s) and the propeller(s). In such plants, the diesel engines are connected directly to generators. The electricity produced by such an engine-driven generator is transmitted, through cables, to a motor. The motor is connected to the propeller shaft directly, or indirectly through a

reduction gear. When a reduction gear is included in a diesel electric drive, the gear is located between the motor and the propeller.

The generator and the motor of a diesel electric drive may be of the alternating current (a-c) type or of the direct current (d-c) type; almost all diesel electric drives in the Navy, however, are of the direct current type. Since the speed of a d-c motor varies directly with the voltage furnished by the generator, the control system of an electric drive is so arranged that the generator voltage can be changed at any time.

9370

An increase or decrease in generator voltage is used as a means of controlling the speed of the propeller. Changes in generator voltage may be brought about by electrical means, by changes in engine speed, and by a combination of these methods. The controls of an electric drive may be in a location remote from the engine, such as the pilot house.

In a d-c electric drive, reversing the direction of rotation of the propeller is not accomplished by the use of a reverse gear. The electrical system is arranged so that the flow of current through the motor can be reversed. This reversal of current flow causes the motor to revolve in the opposite direction. Thus, the direction of rotation of the motor and of the propeller can be controlled by manipulating the electrical controls.

DIESEL ENGINE DRIVE

Diesel engine drive is used on various types of auxiliary ships and craft such as minesweepers, subchasers, ammunition ships, patrol craft, landing ships (LST), and numerous other yard craft and small boats. You may also find diesel drive on a few of the older destroyer escorts.

The Navy uses diesel engines except where special conditions favor the gasoline engine. Standardization of fuels, cheaper fuel, and reduction in fire hazard have been the chief factors in favor of the diesel engine.

The diesel engine used in some of the older destroyer escorts developed approximately 6,000 hp. The diesel engines of minesweepers and subchasers will develop about 1,800 hp; while some of the engines in the smaller yard craft will develop from 190 to 225 hp. A typical diesel engine is shown in figure 4-8.

Some diesel engines are directly reversible. This means that the propeller shaft is directly connected to the diesel engine, so that the speed of the propeller shaft is controlled by the speed of the diesel engine. When it becomes necessary to change direction of rotation of the propeller shaft the diesel engine must be stopped, the cam shaft of the engine shifted for reverse rotation, and then the engine restarted. This allows the engine to operate in the opposite direction; thus reversing the rotational direction of the propeller shaft. You can see that this would take time and be very hard to do if sudden changes in direction were required.

In order to eliminate this stopping-starting situation, and to make a smoother transition from forward to reverse in less time, reverse-reduction gears, clutches, and hydraulic couplings

Figure 4-8.—Typical diesel engine and reduction gear. 75.44X

are used. (These are discussed in the following sections of this chapter.)

CONVERTING POWER TO DRIVE

The basic characteristics of a propulsion unit make it necessary, in most instances, for the drive mechanism to change both the speed and the direction of shaft rotation. In order that both the engine and the propeller may operate efficiently, the engine in many installations includes a device which permits a speed reduction from the engine to the propeller shaft. This device, which is a combination of gears and which effects the speed reduction, is called a reduction gear.

REDUCTION GEARS

Turbines must operate at relatively high speeds for maximum efficiency, whereas propellers must operate at lower speeds for maximum efficiency. Reduction gears are used, therefore, to allow both the turbine and the propeller to operate within their most efficient rpm ranges. A typical reduction gear installation is shown in figure 4-9.

The use of reduction gears is by no means limited to ship propulsion. Other steam turbine-driven machinery, such as ship's service generators, and various pumps also have reduction gears. In these units of machinery as well as in shipboard propulsion units, turbine operating efficiency requires a higher rpm range than that suitable for the driven unit.

Reduction gearing in many current combatant ships makes use of double helical gears. The use of double helical gears produces a smoother action of the reduction gearing and avoids tooth shock. Since the double helical gear has two sets of teeth at complementary angles to each other, the end thrust, such as developed in single helical gears, is thereby eliminated.

Reduction gears are classified by the number of steps used to bring about the speed reduction and the arrangement of the gearing. A gear mechanism consisting of a pair of gears, or a small gear (pinion) driven by the turbine shaft, which drives a large (bull) gear on the propeller shaft directly, is called a SINGLE REDUCTION GEAR. In this type of arrangement, the ratio of speed reduction is proportional to the diameter of the pinion and the gear. For example, in a 2-to-1 single reduction gear, the diameter

139.12

Figure 4-9.—Typical reduction gear installation on upper level of an engine room.

of the driven gear is twice that of the driving pinion; and in a 10-to-1 single reduction gear, the diameter of the driven gear is 10 times that of the driving pinion.

Ships built since 1935 have DOUBLE REDUCTION PROPULSION GEARS. In this type of gear, a high-speed pinion, connected to the turbine shaft by a flexible coupling, drives an intermediate (first reduction) gear which is connected by a shaft to the low-speed pinion; this, in turn, drives the bull gear (second reduction) mounted on the propeller shaft. For example, a 20-to-1 (6000-300) speed reduction might be accomplished by having a ratio of 2 to 1 (6000-3000) between the high-speed pinion and the first reduction gear, and a ratio of 10 to 1 (3000-300) between the low-speed pinion on the first reduction shaft and the second reduction gear on the propeller shaft ($6000 \div 2 = 3000 \div 10 = 300$).

For a typical example of a double reduction application, let us consider the main reduction gear installation on a DD-692 class destroyer, shown in figure 4-10.

The cruising turbine is connected to the high pressure turbine through a single reduction gear. The cruising turbine rotor carries with it a pinion which drives the cruising gear (coupled to the high pressure turbine shaft). The cruising turbine rotor and pinion are supported by three bearings, one at the forward end of the turbine and one on each side of the pinion in the cruising reduction gear case.

9372

47.30

Figure 4-10.—Turbine and locked train double reduction gearing installed on a DD-692 class destroyer.

The high pressure and low pressure turbines are connected to the propeller shaft through a locked-train type double reduction gear, shown in figure 4-11. (Note: This type of reduction gear is used aboard many naval combatant ships.) First reduction pinions are connected by flexible couplings to the turbines. Each of the first reduction pinions drives two first reduction gears. Attached to each of the first reduction gears by a quill shaft and flexible couplings is a second

47.27

Figure 4-11.—Locked train type gearing.

reduction (slow speed) pinion. These four pinions drive the second reduction (bull) gear which is attached to the propeller shaft.

CLUTCHES AND REVERSE GEARS

Clutches are normally used on direct-drive propulsion engines to provide a means of disconnecting the engine from the propeller shaft. In small engines, clutches are usually combined with reverse gears and used for maneuvering the ship. In large engines, special types of clutches are used to obtain special coupling or control characteristics, and to prevent torsional (twisting) vibration.

Reverse gears are used on marine engines to reverse the direction of rotation of the propeller shaft, when maneuvering the ship, without changing the direction of rotation of the engine. They are used principally on relatively small engines. If a high-output engine has a reverse gear, the gear is used for low-speed operation only, and does not have full-load and full-speed capacity. For maneuvering ships with large direct-propulsion engines, the engines are reversed.

Diesel propelling equipment of a boat or a ship must be capable of providing backing-down power as well as power forward. There are a few ships and boats in which backing down is accomplished by reversing the pitch of the propeller; in most ships, however, backing down is accomplished by reversing the direction of rotation of the propeller shaft. In mechanical drives, reversing the direction of rotation of the propeller shaft may be accomplished in one of two ways; by reversing the direction of engine rotation; or by the use of REVERSE GEARS.

More than reducing speed and reversing the direction of shaft rotation is required of the drive mechanism of a ship or a boat. It is frequently necessary to allow an engine to operate without power being transmitted to the propeller. For this reason, the drive mechanism of a ship or boat must include a means of disconnecting the engine from the propeller shaft. Devices which are used for this purpose are called CLUTCHES.

The arrangement of the components depends upon the type and size of the installation. In some small installations, the clutch, the reverse gear, and the reduction gear may be combined in a single unit; in other installations, the clutch and the reverse gear may be in one housing and the reduction gear in a separate housing attached to the reverse gear housing.

In large engine installations, the clutch and the reverse gear may be combined; or they may be separate units, located between the engine and a separate reduction gear; or the clutch may be separate and the reverse gear and the reduction gear may be combined.

In most geared-drive, multiple propeller ships, the propulsion units are independent of each other. An example of this type of arrangement is illustrated in figure 4-12.

In some installations, the drive mechanism is arranged so that two or more engines drive a single propeller. This is accomplished by having the driving gear, which is on—or connected to—the crankshaft of each engine, transmit power to the driven gear on the propeller shaft. In one type of installation, each of two propellers is driven by four diesel engines (quad power unit). The arrangement of the engines, the location of the reduction gear, and the direction of rotation of the crankshaft and the propeller shaft in one type of "quad" power unit are illustrated in figure 4-13.

The drive mechanism illustrated includes four clutch assemblies (one mounted to each engine flywheel) and one gear box. The box contains two drive pinions and the main drive gear. Each pinion is driven by the clutch shafts of two engines, through spines in the pinion hubs. The pinions drive the single main gear, which is connected to the propeller shaft.

Friction clutches are commonly used with smaller, high-speed engines, up to 500 hp. However, certain friction clutches, in combination with a jaw type clutch, are used with engines up

9374

Figure 4-12.—Example of independent propulsion units.

9375

Figure 4-13.—Four engines (quad unit) arranged to drive one propeller (GM 6-71).

to 1,400 hp; and pneumatic clutches, with a cylindrical friction surface, with engines up to 2,000 hp.

Friction clutches are of two general styles; the DISK and the BAND styles. In addition, friction clutches can be classified into dry and wet types, depending upon whether the friction surfaces operate with or without a lubricant. The designs of both types are similar, except that the wet clutches require a large friction area because of the reduced friction coefficient between the lubricated surfaces. The advantages of wet clutches are smoother operation and less wear of the friction surfaces. Wear results from slippage between the surfaces not only during engagement and disengagement, but also, to a certain extent, during the operation of the mechanism. Some wet type clutches are filled with oil periodically; in other clutches the oil, being a part of the engine-lubricating system, is circulated continuously. Such a friction clutch incorporates provisions which will prevent worn-off particles from being carried by the circulating lubricating oil to the bearings, gears, etc.

The friction surfaces are generally constructed of different materials, one being of cast iron or steel; the other is lined with some asbestos-base composition or bronze for dry clutches, and bronze, cast iron, or steel for wet clutches. Cast iron surfaces are preferred because of their better bearing qualities and greater resistance to scoring or scuffing.

The application of force-producing friction to engage the friction clutches can be obtained either by mechanically jamming the friction surfaces together by some toggle-action linkage, or through stiff springs (coil, leaf, or flat-disk type). The operation of friction clutches is discussed in the paragraphs which follow.

TWIN-DISK CLUTCH AND GEAR MECHANISM.—One of the several types of transmissions used by the Navy is the Gray Marine transmission mechanism. Gray Marine high-speed diesel engines are generally equipped with a combination clutch, and reverse and reduction gear unit—all contained in a single housing, at the after end of the engine.

The CLUTCH ASSEMBLY of the Gray Marine transmission mechanism is contained in the part of the housing nearest the engine. It is a dry type, TWIN-DISK clutch with two driving disks. Each disk is connected, through shafting, to a separate reduction gear train in the after part of the housing. One disk and reduction train is for reverse rotation of the shaft and propeller; the other disk and reduction train is for forward rotation.

JOE'S CLUTCH AND REVERSE GEAR.—A typical gear mechanism found on many power boats is Joe's clutch and reverse gear, shown

Figure 4-14.—Cutaway view of Joe's clutch and reverse gear. 75.254

in figure 4-14. The drive from the engine crankshaft is taken into the clutch and reverse gear housing by an extension of the crankshaft drive gear. The crankshaft rotation is transmitted to the reduction gear shaft through the clutch and the reverse gear unit.

AIRFLEX CLUTCH AND GEAR ASSEMBLY.—On the larger diesel-propelled ships, the clutch, reverse, and reduction gear unit has to transmit an enormous amount of power. To maintain the weight and size of the mechanism as low as possible, special clutches have been designed for large diesel installations. One of these is the AIRFLEX CLUTCH and gear assembly used with General Motors 12-567A engines on LST's.

A typical airflex clutch and gear assembly, for AHEAD and ASTERN rotation, is shown in figure 4-15. There are two clutches, one for forward rotation and one for reverse rotation. The clutches, bolted to the engine flywheel, both rotate with the engine at all times, and at engine speed. Each clutch has a flexible tire (or gland) on the inner side of a steel shell. Before the tires are inflated, they will rotate out of contact with the drums, which are keyed to the forward and reverse drive shafts. When air under pressure (100 psi) is sent into one of the tires, the inside diameter of the clutch decreases. This causes the friction blocks on the inner tire surface to come in contact with the clutch drum, locking the drive shaft with the engine.

HYDRAULIC CLUTCHES OR COUPLINGS.—The fluid clutch (coupling) is widely used on Navy ships. The use of a hydraulic coupling eliminates the need for a mechanical connection between the engine and the reduction gears. Couplings of this type operate with a minimum of slippage.

Some slippage is necessary for operation of the hydraulic coupling, since torque is transmitted because of the principle of relative motion between the two rotors. The power loss resulting from the small amount of slippage is transformed into heat which is absorbed by the oil in the system.

Compared with mechanical clutches, hydraulic clutches have a number of advantages. There is no mechanical connection between the driving

Figure 4-15.—Clutch and reverse-reduction gear assembly. 75.247

and driven elements of the hydraulic coupling. Power is transmitted through the coupling very efficiently (97 percent) without transmitting torsional vibrations, or load shocks, from the engine to the reduction gears. This protects the engine, the gears, and the shafting from sudden shock loads which may occur as a result of piston seizure of fouling of the propeller. The power is transmitted entirely by the circulation of a driving fluid (oil) between radial passages in a pair of rotors. In addition, the assembly of the hydraulic coupling will absorb or allow for slight misalignment.

DOG CLUTCHES.—Dog type clutches perform much the same function as the friction type in that they allow the engine shaft to be disconnected from the propeller shaft. The dog clutch ensures

Figure 4-16.—Dog clutches. 75.264

9378

a positive drive without slippage, and with a minimum amount of wear. (Forward drive is generally accomplished by one set of dogs, shown in fig. 4-16, connected to the crankshaft, engaging and turning another set of dogs, connected to the propeller shaft.)

In several installations, the dog clutch is used in addition to a friction clutch; the dog clutch is engaged after the friction (or synchronizing) clutch brings the two shafts to an equal speed. The engagement of the dog clutch eliminates slippage, and holds friction clutch wear to a minimum.

9379

9379

CHAPTER 5

BASIC STEAM CYCLE

In addition to knowing how steam is generated you must know what happens to steam after it leaves the boiler. One of the best ways to learn about the steam plant on your own ship is to trace the path of steam and water throughout its entire cycle of operation. Figure 5-1 is a diagrammatic representation of the basic steam cycle. The water and the steam circulate throughout the entire cycle of operation without ever being exposed to the atmosphere.

This chapter discusses the steam cycle in four basic areas of operation: (1) generation, (2) expansion, (3) condensation, and (4) feed. (Feed is the term used to describe the water supplied to the boiler for the generation of steam.)

GENERATION

To generate steam, it is first necessary to heat water to its boiling point and then add a sufficient amount of heat to change (convert) the boiling water into steam. The heat required to change boiling water into steam, at any given temperature of the boiling water, is called the LATENT HEAT OF VAPORIZATION. When steam condenses back to water (at the boiling point), an equal amount of heat is given off; it is called the LATENT HEAT OF CONDENSATION. The amount of heat required to convert boiling water to steam, or the amount of heat given off when steam is condensed back to water at its boiling temperature, varies with the pressure under which the

Figure 5-1.—Diagrammatic arrangement of the steam cycle.

9380 1860

process takes place. Part A of figure 5-1 illustrates the generation area of the cycle.

There are definite pressure-temperature relationships involved in the generation of steam. The boiling point of water is 212°F at sea level, where the atmospheric pressure is 14.7 psi. At higher altitudes, where atmospheric pressure is reduced, water boils at a lower temperature. If the pressure is increased, the boiling temperature of water will also be increased. In a boiler operating under a pressure of 600 psig, water must be heated to approximately 489°F to make it boil. In boilers operating under a pressure of 1000 psig, water must be heated to approximately 544°F to make it boil. Therefore, the boiling point of water is determined by the pressure.

It is important to note that the temperature of steam is determined by the temperature at which the water boils, as long as the process is taking place in a closed vessel or in a closed system such as a boiler. As long as the pressure remains constant, steam in contact with the water from which it is being formed must remain at the same temperature as the boiling water. Therefore, in a boiler operating under a pressure of 600 psig, the temperature of the steam in the steam drum must be approximately 489°F— the same temperature as the boiling water. (The steam drum of the boiler is a sealed chamber that holds the water and steam.)

The steam in the steam drum is called SATURATED STEAM—this is steam which has not been heated above the temperature of the water from which it was generated. Saturated steam is used aboard ship to operate most of the auxiliary equipment and also in the various types of heaters.

It is impossible to raise the temperature of saturated steam without also increasing the pressure as long as the steam is in contact with the water from which it is formed. However, the steam can be heated above its saturation temperature if it is first drawn off into another vessel, where it is no longer in contact with the water, and additional heat is applied. Steam which has been heated above its saturation temperature is known as SUPERHEATED STEAM. The device which allows this extra heat to be added to the steam is known as a SUPERHEATER. Figure 5-2 shows a simple form of both a boiler and a superheater.

Most naval propulsion boilers are equipped with superheaters. Superheated steam has many advantages over saturated steam for use in propulsion machinery. Because the steam is dry, it causes relatively little corrosion or erosion of piping and machinery. In addition, superheated steam does not conduct heat as rapidly as saturated steam, therefore, it does not lose heat as rapidly. The use of superheated steam for propulsion purposes greatly increases the overall efficiency of the engineering plant; this increased efficiency results in large savings in fuel consumption, and in space and weight requirements.

Since most auxiliary machinery is designed to operate on saturated steam, naval boilers are designed to produce both saturated and superheated steam.

EXPANSION

The expansion portion of the steam cycle is that part of the cycle in which steam is led from the boilers to the main turbines, and expanded in those turbines to remove the heat energy stored in the steam and transform that energy into mechanical energy of rotation. The main steam

Figure 5-2.—Elementary boiler and superheater. 38.3

9381

9380

38.17

Figure 5-3.—Deaerating feed tank.

system is the piping system which leads the steam from the boilers to the main turbines.

The main turbines generally consist of the cruising turbine, high pressure turbine, and the low pressure turbine. The steam may flow into the cruising turbine, then to the high pressure turbine, and on into the low pressure turbine; or the cruising turbine may be bypassed. Some main turbine installations do not have a cruising turbine. Part B of figure 5-1 illustrates the expansion portion of the steam cycle; it contains the cruising turbine, high pressure turbine, and low pressure turbine.

9382

CONDENSATION

Since each ship must produce sufficient quantities of feed water for the boilers and since a marine engineering plant must be as efficient as is possible, the feed water must be used over and over again.

As the steam leaves or exhausts from the low pressure turbine, it enters the condensate system. The condensate system is that part of the steam cycle in which the steam condenses to water and flows from the main condenser toward the boilers while it is being prepared for use as feed water.

The several components of the condensate system, in order, from the low pressure turbine are (1) main condenser, (2) main condensate pump, and (3) the main air ejector. These components are shown in part C of figure 5-1.

The main condenser receives the steam from the low pressure turbine and condenses the steam into water. The main condensate pump takes suction from the main condenser and delivers the condensate into the condensate piping system and through the main air ejector. As its name implies, the air ejector removes the air that was picked up in the main condenser. The condensate, after passing through the air ejector enters the deaerating feed tank.

FEED

The deaerating feed tank (fig. 5-3) is sometimes considered as the dividing line between condensate and feed water. This tank has three basic functions: (1) to free the condensate of all trapped oxygen and air, (2) to heat the water to a degree which will allow the economizer to introduce all the remaining necessary heat before discharging to the boiler, and (3) to act as a reservoir in which to store water to take care of rapid increases in feed needs and to absorb sudden increases or surges of the condensate.

As the condensate enters the deaerating feed tank it is sprayed into the dome of the tank by nozzles. Here it is discharged in a fine spray throughout the steam filled top or preheater. Breaking up the condensate into a fine spray releases the trapped oxygen and air from the condensate. The air-free, oxygen-free condensate falls to the bottom of the tank, while the air and oxygen are exhausted from the tank.

The condensate that is collected in the storage section of the deaerating feed tank is now called feed water and becomes a source of supply for the main feed booster pump. The main feed booster pump takes suction from the deaerating feed tank and maintains a constant discharge pressure to the main feed pump.

The main feed pump picks up the water (delivered from the booster pump) and discharges it into the main feed piping system. Part D of figure 5-1 illustrates the path of the water from the deaerating feed tank to the economizer. The discharge pressure of the main feed pump is usually about 150 psi greater than the boiler operating pressure. For example, the discharge pressure of a main feed pump, discharging to a boiler operating at 600 psi, will normally be 750 psi. The discharge pressure is maintained throughout the main feed piping system; however the quantity of water discharged to the economizer is controlled by a feed stop and check valve or automatic feed water regulator valve.

The economizer is positioned on the boiler to perform one basic function; that is, to act as a preheater. The gases of combustion flow around the economizer tubes which absorb some of the heat of combustion and the economizer in turn heats the water that is flowing through the economizer tubes. As a result the water is approximately 100°F hotter as it flows out of the economizer to the boiler.

CHAPTER 6

BOILERS

This chapter is designed to provide you with basic information on boilers and their operating principles. It includes a discussion on boiler construction and the major parts and their functions. It lists numerous fireroom safety precautions which must be observed when boilers are being fired.

BOILER ASSEMBLY

A boiler is defined as that part of a steam generator in which water is converted into steam. The boiler consists of metal drums, headers and tubes, and accessories that will assist the operator in controlling steam pressure and temperature and other aspects of boiler operation.

You will also find a furnace with casing and uptake; steam and water drums; generating, circulation, and water screen tubes; a superheater; and an economizer; and the necessary piping and accessories to ensure an ample supply of fuel, water, and air.

In the following sections on boiler assembly assume that you are assembling a boiler similar to the one shown in figure 6-1.

The Steam Drum (fig. 6-2) is cylindrical in shape and is located at the top of the boiler. The steam drum runs lengthwise from the front of the boiler to the back. The steam drum provides a space for the accumulation of steam generated in the tubes and for the separation of moisture from the steam. It also serves as a storage space for boiler water, which is distributed from the steam drum to the downcomer tubes. (During normal operation, the steam drum is kept about half full of water.) In addition to these basic functions, the steam drum either contains or is connected to many of the important controls and fittings required for the operation of the boiler.

At the bottom of the boiler you will find another drum and a header, as shown in figure 6-3. The largest drum is the water drum and the other is the header. Both are smaller than the steam drum. They are used to equalize the distribution of water to the generating tubes, and provide a place for the accumulation of loose scale and other solid matter that may be present in the boiler water. Each drum and header is provided with a blowdown valve. When the valve is opened, some of the water is forced out of the drum or header and carries the loose scale, sediment, or dirt with it.

At each end of the steam drum a number of large tubes are installed (fig. 6-4) that lead to the water drum and the sidewall header. These tubes are called downcomers and are utilized to ensure a downward flow of water from the steam drum to the water drum and header. The downcomers range in diameter from 3 to 8 inches.

A great number of other tubes are also installed linking the steam drum to the water drum and the steam drum to the header. These tubes are called generating tubes and are illustrated in figure 6-5. The generating tubes are arranged in the furnace so that the gases and the heat of combustion flow around them. The large arrows in figure 6-5 show the direction of flow of the combustion gases.

The generating tubes are made of steel that is strong enough to withstand the high pressures and temperatures within the boiler. In most boilers the water tubes are from 1 to 2 inches in diameter. These small tubes present a large surface area to absorb the heat in the furnace. Note that a 2" (ID) tube has twice the surface area of a 1" tube, but 4 times the volume. A 3" tube has three times the surface area of a 1" tube but 9 times the volume. The smaller the diameter of the tube, the higher is the ratio of absorption surface to the volume of water.

Normally there is only one row of tubes between the steam drum and the sidewall header. This single row of tubes is used to provide a cooling effect that protects the side wall of the furnace.

9384

Figure 6-1.—Cutaway view of a D-type boiler (older type). 38.40

So far we have assembled the drums, header, downcomers, and the generating tubes. Before going any further with the assembly trace the path of the water through the boiler. The water flows out of the steam drum down through the downcomers into the water drum and the side-wall header. As the water is heated it forms a vapor (steam) that is lighter than the water in

Figure 6-2.—Steam drum. 139.13

Figure 6-6.—Natural circulation (accelerated type). 139.17

which it is contained; this will cause it to rise and return to the steam drum via the generating tubes, as steam. Figure 6-6 illustrates the circulation path of the boiler water from the steam drum.

In order to heat the water that we have contained in the drums, tubes, and headers a space is provided for the mixing of air and fuel and for the combustion of the fuel (fire). This space is called the furnace or firebox and is shown in figure 6-5.

The boiler furnace consists of a more or less rectangular steel casing which is lined on the floor, front wall, side walls and rear wall with refractory (heat resisting) material. The refractory material that is used in naval boilers

38.40

Figure 6-7.—Refractory lined furnace.

includes firebrick, insulating brick, plastic firebrick, and air-setting mortar.

The refractory lining serves to protect the furnace steel casing, and to prevent the loss of heat from the furnace. The refractories retain heat for a relatively long time and thus help to maintain the high furnace temperatures necessary for complete combustion of the fuel. Figure 6-7 shows a refractory lined furnace.

There are many different types of refractories; but their use is determined by their physical and chemical properties and specific location within the furnace. Some refractory materials can withstand greater temperatures than others

139.18

Figure 6-8.—Relative position of economizer.

and will be positioned nearer to the intense heat of the fire.

In chapter 5 you discovered that an economizer is positioned on the boiler and that it acts as a heater in that it absorbs the heat of combustion and transmits this heat to the incoming feed water. The economizer is positioned on the boiler as shown in figure 6-8, and is made up of a number of tubes which are illustrated in figure 6-9. The fins on the tube absorb the heat from the gases of combustion and in turn transfer the heat to the incoming feed water.

One more basic component is needed to complete the water-steam flow path. From your study of the steam cycle do you remember what that

38.28

9388

Figure 6-13.—Return-flow atomizer. 38.75

component might be? In chapter 5 you were told that the steam, as it leaves the steam drum on its way to the main turbines, passes through a superheater.

The superheater is constructed of a number of U-shaped tubes (fig. 6-10) which are installed horizontally projecting forward into the furnace. The superheater tubes are connected to the superheater headers (fig. 6-10) which are installed vertically at the rear of the boiler; one end of the tube enters one header and the other end of the tube enters the other header. (Some superheaters are of the vertical type with horizontal headers.)

The superheater tubes are positioned in the boiler so that they are surrounded by the generating tubes and where the hot gases of combustion will flow over and around them. Figure 6-11 shows the relative position of the superheater tubes installed in the boiler. The major parts of the boiler have now been assembled. Look again at the assembled boiler shown in figure 6-1, identify the component parts, and review their functions.

38.71

Figure 6-14.—Parts of a straight-through-flow atomizer assembly.

FUEL OIL BURNERS

With the major components of the basic boiler assembled, a means must be provided for the proper mixing of the fuel and air and to allow for the entry into the furnace. This is accomplished by the fuel oil burners that are mounted on the boiler front (fig. 6-12). The complete burner assembly consists of the atomizer, the air registers, and the valves and fittings needed to connect the atomizer to the fuel line.

ATOMIZERS

The atomizers divide or break up the fuel oil into very fine particles as illustrated in figure 6-13. At present there are three major types of atomizers in use on naval boilers. Straight-through-flow atomizers are the most common. The return-flow atomizers (fig. 6-13) are used on many of the newer ships; you may also find steam-assist atomizers on some of the newer ships.

Figure 6-14 shows an atomizer of the straight-through-flow type. It consists of five major parts; the tip, sprayer plate, nozzle, burner barrel, and the goose neck. The nozzle-sprayer plate-tip assembly fits on the end of the burner barrel which projects into the furnace. The goose neck fits on the outer end of the burner barrel where it provides a means for the fuel oil to enter the atomizer and into the furnace.

AIR REGISTERS

The air register permits the air to enter the furnace in such a way that it mixes with the fine oil spray as shown in figure 6-13. Figure 6-15 shows the arrangement of air register parts in a burner assembly. The air register consists of three main parts: (1) air doors, (2) a diffuser, and (3) air foils. The air doors serve to open or close the register as necessary. They are usually kept either fully open or fully closed. When the air doors are open, air rushes in and is given a whirling motion by the diffuser plate. The diffuser plate causes the air to mix evenly with the atomized oil, in such a way as to prevent the flame from being blown away from the atomizer.

38.69

Figure 6-15.—Cross-sectional view of Babcock and Wilcox Carolina-type fuel oil burner with straight-through-flow atomizer.

The air foils guide the major quantity of air and cause it to mix with the larger particles of oil spray beyond the diffuser.

Oil is forced under pressure through the burner barrel. It goes through the holes in the nozzle (part A of fig. 6-16) into the tangential slots of the rear side of the sprayer plate (part B of fig. 6-16). These slots are so shaped that the oil is given a high rotational velocity as it discharges into a small cylindrical "whirling chamber" in the center of the sprayer plate (part B of fig. 6-16).

9390

38.72X-.74

Figure 6-16.—Nozzle and sprayer plate showing holes, slots and whirling chamber.

The whirling chamber is cone-shaped at the end, and has an opening (orifice) at the small end of the cone. As the oil leaves the chamber by way of this orifice, it is broken up into very fine particles which form a cone-shaped fog-like spray. A strong blast of air, which has been given a whirling motion in its passage through the register, catches the oil fog and mixes with it. The mixture of air and oil enters the furnace, where combustion takes place.

CLASSIFICATION OF BOILERS

Naval boilers may be classified in a number of different ways, according to various design features. Some knowledge of these methods of classification will be useful in understanding the design and construction of modern naval boilers.

LOCATION OF FIRE AND WATER SPACES

First of all, boilers are classified according to the relative location of their fire and water spaces. By this method of classification, all boilers may be divided into two groups: FIRE-TUBE BOILERS and WATER-TUBE BOILERS. In fire-tube boilers, the gases of combustion flow through the tubes and heat the surrounding water. In water-tube boilers, the water flows

38.38X

Figure 6-17.—Cutaway view of M-type divided furnace boiler.

through the tubes and is heated by the gases of combustion that fill the furnace.

All boilers used in propulsion plants of naval ships are water-tube boilers. Fire-tube boilers, which were once used extensively in marine installations, are still used in propulsion plants of some older merchant ships. However, these boilers are not suitable for use on modern naval ships because of their excessive weight and size, the excessive length of time required to raise steam, and their inability to meet demands for rapid speed changes. Auxiliary boilers are not generally used on steam-driven ships because all steam for auxiliary service is taken from the propulsion-plant boilers.

TYPES OF CIRCULATION

Water-tube boilers are also classified according to the type of circulation. Natural circulation boilers are those in which the circulation of water depends upon the difference in density between an ascending mixture of hot water and steam, and a descending body of relatively cool and steam-free water. The difference in density occurs because the water expands as it is heated, thus becoming less dense. There are two types of natural circulation—FREE and ACCELERATED.

In FREE circulation boilers, the tubes which connect the lower and upper drums or headers are only slightly inclined; this allows the lighter hot water and steam to rise while the heavier and cooler water descends. Installing the generating tubes at a greater angle of inclination increases the rate of water circulation. Therefore, boilers in which the tubes slope more steeply between the water drums or headers and the steam drum are said to have ACCELERATED natural circulation.

Most modern naval boilers are designed for accelerated natural circulation. In such boilers, large tubes (3 inches or more in diameter) are installed between the steam drum (located at the top of the boiler) and the water drums (located at the bottom of the furnace). These large tubes, known as downcomers, are located outside the furnace and away from the heat of combustion, thereby serving as pathways for the downward flow of relatively cool water. The small tubes (generating tubes) then carry the steam and water upward.

TYPE OF SUPERHEATER

On practically all boilers currently used in the propulsion plants of naval ships, the superheater tubes are protected from radiant heat by water screen tubes. These tubes absorb the intense radiant heat of the furnace, and the superheater tubes are heated by convection currents rather than by direct radiation. Hence, the superheaters are referred to as CONVECTION-TYPE SUPERHEATERS.

On some older boilers, the superheater tubes were not screened by water screen tubes but were exposed directly to the radiant heat of the furnace. Superheaters of this type are called RADIANT-TYPE SUPERHEATERS. Although this type of superheater is uncommon at the present time, it may be used again in future boiler designs.

FURNACE ARRANGEMENT

All natural circulation boilers now in naval use may also be classified according to the furnace arrangement. By this classification, boilers are either SINGLE-FURNACE BOILERS or DOUBLE-FURNACE BOILERS. Double-furnace boilers are also referred to as DIVIDED-FURNACE BOILERS.

OTHER NAVAL BOILERS

There are many different kinds of boilers used in naval ships. Earlier in this chapter you studied and assembled the 600 psi D-type boiler. Some of the other boilers used in naval ships are the 600 psi M-type divided-furnace boiler shown in figure 6-17 and the 1200 psi boiler shown in figure 6-18. Notice that the boiler shown in figure 6-18 is very similar to the boiler shown in figure 6-1. However the boiler in 6-18 has some special operating and design features which make it different from the one shown in figure 6-1. On some older ships you may find the sectional header boiler, which is illustrated in figure 6-19. A relatively new boiler that is presently installed on some new construction of the DE 1040 class is the pressure fired boiler shown in figure 6-20. Since the pressure fired boiler is used for propulsion only, those ships that have a pressure fired boiler installed, also have an auxiliary boiler.

In addition to the boilers that are used for main propulsion there are also auxiliary boilers. The term auxiliary boilers is used to include a wide variety of small boilers which are used in diesel-driven ships to supply steam or hot water for distilling plants, space heating, galley and laundry services. Auxiliary boilers are equipped with the accessories and controls necessary for their operation as a complete self-contained

Figure 6-18.—1200 psi single-furnace boiler.

Figure 6-19.—Cutaway view of a sectional header boiler. 38.33X

unit. The three basic types of auxiliary boilers in naval use are: (1) fire-tube boilers, illustrated in figure 6-21, (2) water-tube boilers with natural circulation, shown in figure 6-22, and (3) water-tube boilers with forced circulation, as shown in figure 6-23.

Generally, operating pressures of auxiliary boilers range from 50 psi to 125 psi. Most operating and maintenance procedures for main propulsion boilers are also applicable to auxiliary boilers.

NEW HIGH PRESSURE BOILERS

The modern trend in boiler design is toward higher pressures and temperatures. High pressure boilers have the advantage of being smaller, lighter, and more economical of fuel for any given shaft horsepower than boilers which operate at lower pressures and temperatures. Boilers operating at 4500 psi and above are now in use in some stationary steam power plants. For naval propulsion boilers, such pressures are

9395

139.19

Figure 6-20.—Pressure fired boiler.

9396

139.20

Figure 6-21.—Fire tube auxiliary boiler.

not practicable at the present time. However, a number of boilers, operating at 1200 psi pressure and at 950°F, have been installed on new naval ships; increasing use will probably be made of these boilers.

The term HIGH PRESSURE BOILER refers to any boiler operating at 700 psi or above. The term HIGH PRESSURE, D-TYPE BOILER refers to a natural circulation boiler that is the same as the D-type boiler, except that it has been modified for higher operating pressures.

FIREROOM SAFETY PRECAUTIONS

Safety precautions are for your protection as well as for the protection of the machinery and equipment. When working in a steaming fireroom you should be fully clothed. The valves, pipes and exposed metal in firerooms are always hot and will burn the flesh and leave a scar. It is advisable not only to keep your shirt on; but to keep the shirt sleeves rolled down. Whenever you are assisting in lighting off or securing boilers, or just generally working in the fireroom, pay strict attention to posted safety precautions and to those precautions that your petty officers will tell you.

A few important safety precautions are listed here; your petty officers will instruct you in many more:

1. Do not open or close any valve whose purpose you do not understand and which you were not told to open or close.

9397

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

139.22

Figure 6-23.—Assembly view of a forced circulation auxiliary boiler.

2. Do not play games of any kind in the fireroom.

3. Do not leave tools lying around the fireroom; always return them to their proper stowage.

The following precautions should be observed when lighting off a boiler:

1. Run the water level down until it is below lighting off level and then add water with the emergency feed pump until it is at lighting off level.

2. Always purge the furnace before lighting off the first saturated burner.

3. Stand well clear when inserting and withdrawing the torch.

The following precautions should be observed during boiler operation.

1. Never leave disconnected atomizers in place.

2. Keep the atomizer root valves to secured burners closed, except during maneuvering.

3. Test the drain from the oil heater once each hour.

4. Blow through the gage glasses once each watch.

5. Poke through the burner drain holes once each watch.

6. Wipe up spilled oil at once.

The following safety precautions apply to securing a boiler:

1. In shutting down a fireroom, do not close the master oil valve until the fuel oil pump is secured.

2. Remove atomizers from registers as soon as possible after securing.

3. Close all openings to the furnace as soon as all atomizers have been extinguished.

4. Pump the water level to three-fourths of a glass on cutting out a boiler.

9399

136

CHAPTER 7

STEAM TURBINES AND REDUCTION GEARS

Earlier chapters of this training course presented the basic steam cycle and various turbine propulsion units. This chapter will lift the cover from the turbines and the reduction gears so that you may obtain a basic understanding of how the stored energy (heat) in steam is transformed into the mechanical energy (work) of rotation.

TURBINES

The development of steam power was built around the reciprocating engine; however, the earliest steam engine operated on the TURBINE principle. Almost 2,000 years ago a Greek mathematician named Hero built a small steam turbine and demonstrated the feasibility of steam power (fig. 7-1). Hero's turbine consisted of a hollow sphere which carried four bent nozzles. The sphere was free to rotate on the tubes that carried steam from the boiler. Steam generated in the boiler passed up the tubes into the sphere and out through the nozzles. The action of the steam leaving the nozzles caused the sphere to rotate rapidly.

139.23

Figure 7-1.—Hero's steam turbine.

Down through the ages the turbine principle has been applied to many different types of machines. The water wheel that was used to operate the flour mills of colonial times, the common windmill used for pumping water, and the two-bladed windmill used for charging batteries are all examples of applications of the turbine principle. In these examples the power is derived from the effect of the wind or a stream of water on a set of blades attached to a wheel. In the steam turbine, steam under pressure serves the same purpose as the wind or the flowing water in the other types.

CLASSIFICATION OF TURBINES

Turbines may be classified in four ways:

1. The manner in which the steam causes the turbine rotor to rotate.
2. The type of staging and compounding of steam pressure and velocity.
3. The division of the steam flow.
4. The direction of the steam flow.

Under each of these classifications, there are several types of turbines, some of which are described briefly in the following paragraphs.

Impulse Turbines

The energy to rotate an impulse turbine is derived from the kinetic energy of a steam jet or some other rapidly moving fluid. The term "impulse" infers that the force which turns the turbine is derived from the impact of the

Figure 7-2.—The toy pinwheel operates on the impulse turbine principle. 139.24

fluid. The toy pinwheel (fig. 7-2) can be used to study some of the basic principles of turbines. When you blow on the rim of the wheel, it spins rapidly. The harder you blow, the faster it turns. The steam turbine operates on the same principle, except that it uses the high pressure steam from the ship's boiler.

The impulse turbine consists essentially of a rotor or spindle mounted on a shaft that is free to rotate in a set of bearings. The outer rim of the spindle carries a set of curved blades, and the whole assembly is enclosed in an air-tight case. Several nozzles direct the steam against the blades and turn the spindle (fig. 7-3).

STEAM NOZZLES are connected to the line that caries high pressure steam from the boiler. As the steam passes through each nozzle, its pressure is reduced, but its velocity is greatly increased. The potential energy of the steam under pressure is converted to kinetic energy in the high-speed jets emerging from the nozzles. These jets are directed against the nozzles. These jets are directed against the turbine blades and turn the spindle. To be more explicit, the velocity of the steam is reduced in passing over the blades, and some of its kinetic energy is transferred to the blades as a force that is utilized to turn the spindle. The modern impulse turbine operates on the same general principle as the model just described, but it has many refinements.

COMPOUND TURBINES have several rows of revolving blades with stationary nozzles or blades mounted between each row. As the steam passes through the first stage, it speeds up in the nozzles and slows down while going through the moving blades. The second set of nozzles speeds it up again, making additional kinetic

33.46

Figure 7-3.—A simple impulse turbine.

139.25

Figure 7-4.—A velocity compound impulse turbine with a reduction gear.

9401

energy available for the second row of moving blades. This sequence continues through all of the successive stages until the pressure is reduced to the point where it would not be feasible to extract any more energy from it.

The velocity compound impulse turbine shown in figure 7-4 has two rows of moving blades. Steam enters through the inlet, flows through the governor valve, and passes through the stationary nozzles. There is a large pressure drop and a large velocity increase out of the nozzles. The steam enters the first row of moving blades attached to the spindle where there is a decrease in velocity. It then flows through the stationary blades or guide blades. There is neither a pressure drop nor a velocity increase while the steam goes through the stationary blades; they merely provide a reversal of steam flow prior to entering the next row of moving blades. The steam then enters the second row of moving blades where there is also a decrease in velocity. The velocity is reduced so that by the time the steam reaches the exhaust, most of the energy has been utilized to turn the spindle.

The shaft of the spindle revolves in bearings supported by the turbine casing. Carbon packing rings keep the steam from escaping through the shaft bearing. The reduction gear (discussed later in the chapter) consists of a pinion attached to the spindle shaft and a much larger bull gear. Because of its larger diameter, the bull gear rotates much more slowly than the high-speed turbine.

Impulse turbines are used in the Navy to drive the forced draft blowers and most of the feed water and fuel pumps. They have few moving parts, are lightweight, do not take up much space, and run with very little vibration.

In an impulse turbine, a STAGE is defined as one set of nozzles and the succeeding row or rows of moving and fixed blades. Another way of defining a stage is to say that it includes the nozzles and blading in which only one pressure drop takes place. (In an impulse turbine, remember, the only pressure drop takes place in the nozzles. Therefore, the number of sets of nozzles in an impulse turbine indicates the number of stages.)

Figure 7-5 shows a SIMPLE IMPULSE TURBINE. This turbine has one stage, consisting of one set of nozzles and one row of moving blades mounted on the rotor. Simple impulse turbines do not completely utilize the velocity of the steam, and are therefore not very efficient.

One way to increase the efficiency of a single stage impulse turbine is to add another row (or even two more rows) of moving blades to the rotor wheel. Figure 7-6 shows a turbine which has two rows of moving blades. This type of turbine is called a VELOCITY-COMPOUNDED IMPULSE TURBINE because the residual velocity of the steam leaving the first row of moving

38.78X

Figure 7-5.—Simple impusle turbine.

Figure 7-6.—Velocity-compounded impulse turbine. 38.79X

9402

blades is utilized in the second row of moving blades; and, if a third row is added, the velocity of the steam is utilized again in the third row. The fixed blades, which are fastened to the casing rather than to the rotor, serve only to direct the steam from one row of moving blades to another.

Another way to increase the efficiency of an impulse turbine is to arrange two or more simple impulses stages in one casing. The casing is internally divided by diaphragms which contain nozzles so that the residual steam pressure of one stage is utilized in the following stage. This type of turbine is known as a PRESSURE-COMPOUNDED IMPULSE TURBINE because a pressure drop occurs in each stage, as the steam expands through each set of nozzles. Figure 7-7 shows a pressure-compounded impulse turbine with four stages.

38.80X

Figure 7-7.—Pressure-compounded impulse turbine.

Reaction Turbines

The ancient turbine built by Hero operated on the reaction principle. Hero's turbine was invented long before Newton's time, but it was a direct application of Newton's third law of motion which states: FOR EVERY ACTION THERE MUST BE AN EQUAL AND OPPOSITE REACTION. On first thought, you may find it difficult to accept this statement on its face value. However, an examination of a few common examples should make you realize that it is true.

If you set an electric fan on a roller skate, it will take off across the table (fig. 7-8). The fan pushes the air and sets up a breeze; the air is also pushing on the fan with an equal force, but in an opposite direction.

139.26

Figure 7-8.—The reaction of the air on the blades rolls the electric fan across the table.

When you try to push a car, you may not know it but you are pushing back with your feet as hard as you are pushing forward with your hands. Try it sometime when you are standing on an icy road. With a little thought on your part you should be able to come up with enough examples to prove to yourself that Newton's third law of motion holds true under all circumstances.

The reaction turbine uses the reaction of a steam jet to drive the spindle. When discussing the impulse turbine, we explained that the nozzles increased the velocity of the steam and transformed the potential energy of the steam under pressure into kinetic energy in the steam jet. A forward force must be applied to the steam to increase its velocity as it passes through the nozzle. From Newton's third law of motion we know that the steam jet exerts an equal reactive force on the nozzle and on the turbine blades, but in the opposite direction; this is the force that drives the turbine.

139.27

Figure 7-9.—A toy balloon demonstrates the "kickback" or reaction principle.

SOAC

In the reaction turbine, stationary blades attached to the turbine casing act as nozzles and direct the steam to the moving blades. The moving blades are mounted on the rotor. Most reaction turbines have several stages, with alternate rows of stationary and moving nozzle blades.

The "kickback" or reaction force generated by the nozzle blades can be demonstrated by a toy balloon. Blow up the balloon and toss it into the air. The air will rush out through the opening and the balloon will shoot off in the opposite direction (fig. 7-9).

When the balloon is filled with air, we have potential energy by virtue of the increased air pressure inside. The air that escapes is speeded up as it passes out through the small opening; this represents a transformation from potential to kinetic energy. The force applied to the air to speed it up is accompanied by a reaction in the opposite direction. This reactive force propels the balloon forward through the air.

You probably think that the propelling force comes from the jet of air blowing against the air in the room, but this is not so. It is the reaction of the force required to increase the velocity of the air as it passes out through the opening. The balloon would travel even faster if it were in a vacuum.

The reaction type turbine (fig. 7-10) has all the advantages of the impulse type turbine, plus a slower operating speed and greater efficiency. The several stages through which the steam passes gradually reduce the steam pressure until practically all of the energy has been converted to power. When operated in conjunction with a condenser, the exhaust pressure of the turbine is only a small fraction of the normal atmospheric pressure. The steam gradually expands as it passes through the successive stages. The additional volume of the steam due to this expansion is taken care of by increasing the diameter of the spindle in each stage.

In the REACTION TURBINE, the steam pressure successively drops in each row of blades (whether fixed or moving). The combination of a row of fixed blades with a row of moving blades in these turbines is sometimes referred to as a DOUBLE STAGE (also known as a single REACTION STAGE).

The PRESSURE-COMPO)NDED REACTION TURBINE (all reaction turbines are pressure compounded) employs alternate rows, or stages, of fixed and moving blades which compound the total pressure drop into as many steps as there are rows of such blades. This pressure staging lowers the steam velocity in each stage.

139.28X

Figure 7-10.—A low pressure reaction turbine with the upper half of the case removed.

CONSTRUCTION OF TURBINES

Exclusive of the controls, the turbine parts which are common to impulse and reaction turbines include foundations, casings, mozzles (or stationary blades), wheels and rotors, blading, bearings, shaft glands, and gland seals.

Foundations

Turbine foundations are built up from strength members in the hull so as to provide a rigid supporting base. All turbines are subject to varying degrees of temperature—from that existing during a secured condition to that existing during full power operation. Some means must therefore be provided to allow for expansion and contraction.

Normally the after end of the turbine is firmly secured to the structural foundation. The bolts have shanks which are fitted to the exact size of the holes in which they are placed. The tight fit thus prevents motion of any kind.

At the forward end of the turbine, freedom of movement is accomplished by one of two methods. Either elongated boltholes or grooved sliding seats may be used to allow the forward end of the turbine to move fore and aft, as expansion and contraction take place.

9404

47.13X

Figure 7-11.—Diagram of a nozzle group.

Casings

Turbine casings are generally constructed of cast carbon steel; however for the turbines utilizing superheated steam with temperature above 650°F, the casings are generally cast or fabricated from carbon molybdenum steel or chromium molybdenum steel. Each casing has a steam chest which receives the incoming high pressure steam and delivers the steam to the first set of nozzles or blades.

Nozzles

The primary function of the nozzle is to convert the thermal energy of steam into kinetic energy. The secondary function of the nozzles is to direct the steam against the blades. In most modern turbines the nozzles are made up in groups or blocks with each group being controlled by a separate nozzle control valve. The quantity of steam delivered to each stage thus becomes the function of the number of nozzles and nozzle control valves in use. A diagrammatic arrangement of a nozzle group is shown in figure 7-11.

Turbine Rotors

The rotors (forged wheels and shaft) are made of carbon steel for use with steam of relatively low temperatures; however if the temperature of the steam to be used is greater than 650°F then the rotors are made of carbon molybdenum or some other creep- resistant alloy. The primary purpose of the rotor is to carry the moving blades which receive the energy from the steam and turn the turbine shaft. A rotor without the blades is shown in figure 7-12.

Blading

The blades are secured to the turbine casings and rotors by various methods. Some of the methods of securing turbine blading are illustrated in figure 7-13, parts A through D. The straight circumferential dovetail (part A) is primarily used for securing rotor blades. The inverted circumferential dovetail (part B) is used to secure blading in most impulse turbines. The side-locking key piece method, (part C) which is used only on casing blades, consists of driving a locking key piece between the blade root and a groove in the casing. The sawtooth serration method (part D) is used for both rotor and casing blades.

Other component parts of construction or assembly such as the turbine bearings, shaft glands, and the gland sealing system are discussed in the following sections of this training course.

TURBINE BEARINGS

The rotor of every turbine must be supported in bearings, which serve the double purpose of carrying the weight of the rotor and maintaining the correct radial clearance between rotor and casing. All main turbines, and most auxiliary units, have a bearing at each end of the rotor.

Bearings are of two classes: sleeve bearings and antifriction bearings. The latter, which include ball and roller bearings, are used on some small auxiliary units. All propulsion and most auxiliary turbine installations are equipped with

47.15X

Figure 7-12.—Turbine rotor without blades.

9405

Figure 7-13.—Methods of securing turbine blading. 47.16X

Figure 7-14.—A typical propulsion turbine journal bearing.

96.3X

sleeve bearings, which are of two types: cylindrical and spherical-seated. A typical cylindrical journal bearing is shown in figure 7-14. Notice that the upper half and the lower half fit snugly together around the shaft.

THRUST BEARINGS take care of any axial thrust which may exist in a turbine rotor and also hold the turbine rotor within certain definite axial clearances. Thrust bearings are installed on all main turbines. These bearings are installed on one end of the turbine, usually just forward of the forward turbine bearing. A thrust bearing is also installed on the propeller shaft either at the forward end of the main reduction bull gear or in the propeller line shafting abaft (behind) the gear, to take the thrust of the propeller. Except that the propeller thrust bearing is much larger, the design of turbine thrust bearings and propeller thrust bearings is much the same. Thrust bearings are lubricated by the same lubricating oil system which supplies oil to the turbine bearings and reduction gears. An assembled thrust bearing element is shown in figure 7-15.

139.29X

Figure 7-15.—Assembled thrust bearing element.

SHAFT GLANDS

Shaft glands are used to keep steam from leaking out of the turbine casing at the points where the shaft extends through the casing. The shaft glands on auxiliary turbines have a gland housing which may be either a part of the turbine casing or a separate housing bolted to the casing. Two types of packing are used— labyrinth packing and carbon packing. They may be used either separately or in combination.

Labyrinth packing, shown in part A of figure 7-16, consists of rows of metallic strips or fins. These strips are fastened to the gland liner in such a way as to make a very small clearance between the strips and the shaft. As the steam from the turbine casing leaks through the small spaces between the packing strips and the shaft, its pressure is gradually reduced.

Carbon packing rings, shown in part B of figure 7-16, restrict the passage of steam along the shaft in much the same manner as do the labyrinth packing strips. They are mounted around

47.17X

Figure 7-16.—Turbine rotor shaft glands: A. Labyrinth packing gland. B. Carbon packing gland.

the shaft and held in place by springs. Three or four carbon rings are generally used in each gland. Each ring is fitted into a separate compartment of the gland housing, and each ring consists of two, three, or four segments which are butt-joined to each other. Lugs or stop pins are used to keep the carbon rings from rotating with the shaft. The outer carbon ring compartment is connected to a drain line.

Carbon packing is suitable only for relatively low pressures and temperatures. Therefore, when both types of packing are used in one gland, the labyrinth packing is used at the initial high-pressure area and the carbon packing is used at the low pressure area.

GLAND SEALING SYSTEM

In order to seal the glands of the turbines and prevent air from being drawn into the condenser, steam is passed into the glands. The low pressure turbine, which operates at all times with a vacuum in its casing, must have steam admitted at all times to the glands, from some external source. This steam is led from the auxiliary exhaust line, passes through a cutout valve, then through a weight-loaded pressure regulating valve, and finally to the turbine glands.

Figure 7-17.—A turbine steam sealing gland.

The weight-loaded pressure regulating valve operates at all times to maintain a pressure of about 2 psi (17 pounds absolute) to the turbine glands (fig. 7-17). In high pressure and cruising turbines at higher speeds, the pressure on the turbine end of the forward glands will be so great that steam will bleed out through these glands, automatically sealing them. Since these glands may at times seal themselves, it is necessary to have a separate system for the cruising and high pressure turbines.

REDUCTION GEARS

Chapter 4 of this training course discussed the main propulsion locked-train type, double

Figure 7-18.—Articulated type of double reduction gearing. 47.28

9408

47.29

Figure 7-19.—Nested type of double reduction gearing.

reduction gearing used in the DD-692 class destroyer. There are two other types of main propulsion double reduction gearing in use—the articulated gearing and the nested gearing.

The articulated gearing, shown in figure 7-18, has more bearings and occupies more longitudinal space in a ship than the nested or locked-train type reduction gearing. This type is seldom used in the Navy; it is not used on combatant ships.

The nested gearing is the simplest of all double reduction gears. It uses a minimum number of bearings and flexible couplings. The nested type gearing is illustrated in figure 7-19. This type is used on most auxiliary ships; it is not used on combatant ships.

The gearing used in shipboard pumps and auxiliary machinery is not as complicated as the reduction gearing used for main propulsion. Figure 7-20 illustrates common forms of gears used in shipboard machinery. Probably one of the simplest types of reduction gearing is the worm gear shown in figure 7-20.

Worm gears are used for transmitting motion between shafts that are at right angles to each other. The worm consists of a cylinder with one or more threads (single, double, triple) cut on the outside like a screw. The worm wheel is a gear with teeth cut on the outside rim to mesh with the threads on the worm.

The function of the worm gearing is speed reduction. A complete turn of the worm turns the wheel ahead the distance of one tooth on the wheel. A double thread worm will revolve the gear twice as fast as a single thread worm.

REDUCTION GEAR CONSTRUCTION

The gears in a main reduction gear unit such as the main gears and the pinion gears, must be capable of transmitting tremendous power loads. The pinion gear is the smaller of two meshing gears and is used mainly for decreasing speed and increasing power. Since even very slight unevenness of tooth contour and spacing would cause the gears to operate noisily, or even fail, special precautions are taken to manufacture the gears to exact dimensions. The gears are cut in a room where the temperature and the humidity are kept constant. This eliminates expansion and contraction and oxidation of the metal during cutting operations.

Almost all pinion gears in main reduction gearing are completely machined out of specially heat-treated nickel steel forgings. The gear wheels are generally of built-up construction, with the teeth cut in forged steel bands which are welded to steel webs. The first reduction gears are generally welded on their respective shafts. The bull gear is usually pressed on the shaft against a locating shaft shoulder and is, secured by one or more keys and a locking nut. Figure 7-21 illustrates the key and locking nut mechanism.

The gear casings can be divided into three major parts. The lower part (the base section)

Figure 7-20.—Types of gears found in shipboard machinery. 5.22

Figure 7-21.—Key and locking nut. 139.30

is used to support the bull gear, main thrust bearing, and the high speed parts of the reduction gear. The lower section also serves as the sump or storage tank for the lubricating oil in the system. The intermediate section of the casing supports the bearing housing for the intermediate speed pinions and gears as well as the high speed pinions. The other part of the gear casing is the main cover which is divided into two sections which have inspection ports that are located so that the teeth of any pinion or gear can be examined without removing the main cover sections. The inspection ports are covered by easily opened hinged covers.

Reduction gearing for pumps and other auxiliary machinery is constructed slightly different than the main reduction gearing just discussed. In the ship's service generator, the pinion is forged together with the shaft as one whole part. One end of the pinion shaft is flanged and bolted rigidily to the turbine shaft. The gear wheel is pressed and keyed onto the shaft.

In main circulating pumps the pinion is a solid forging, while the gear is constructed by welding a forged hub and a forged rim together. The gear hub is bolted to a plate which is keyed to the gear shaft.

The reduction gear of a turbine-driven condensate pump, shown in figure 7-22, which is a worm shaft and a worm wheel, reduces the turbine speed of approximately 5500 rpm to the pump speed of approximately 1100 rpm. The worm is cut in a solid, low-carbon, nickel-steel forging. The worm wheel is a solid nickel-bronze casting which is pressed onto a forged steel shaft. The gear casing is of cast steel designed to form rigid support for the rotating elements and is split horizontally to allow assembly and disassembly.

LUBRICATION

All moving surfaces must receive a steady and adequate supply of oil of proper quality at the correct temperature and free of any foreign matter. In addition, a means must be provided for impurities from the lubrication system and for maintaining a reserve supply of good clean oil.

To understand the principles of lubrication you should know the purposes of a lubricant. Lubricants reduce friction between moving parts. Friction may be defined as the resistance to motion offered by the surfaces of two bodies in contact. When this frictional resistance is overcome, and motion takes place, heat is generated. There are three kinds of friction:

Figure 7-22.—Main condensate pump reduction bearing. 47.38

1. SLIDING FRICTION—between two solids whose opposing surfaces slide over each other.
2. ROLLING FRICTION—between two solids, one (or both) of which is rolling on the other.
3. FLUID FRICTION—between the molecules or particles of a fluid, or between two films of fluid.

Since liquid lubricants can be readily circulated, they are universally used for internal lubrication. Lubricating oils are mineral oils obtained from petroleum. In theory, fluid lubrication is based on the actual separation of the surfaces so that no metal-to-metal contact occurs. As long as an oil film remains unbroken, sliding or rolling friction is replaced by the fluid friction (internal friction) of the lubricant itself. Under such ideal conditions, friction and wear are held to a minimum.

Purpose of Lubrication

The primary purpose of lubricating oil and grease is to substitute fluid friction for either of the other types of friction. This means that a lubricant of sufficient quantity and consistency must be provided to keep the moving metal parts (of bearing, lining, and journal, for example) from contacting each other. The remaining fluid friction, within the lubricant itself, is far less than that which would otherwise occur between the solids, but it also generates heat which must be removed.

This brings you to the secondary but highly important purpose of a lubricant, that of ABSORBING AND REMOVING THE HEAT which is generated by the fluid friction and the heat which, in steam turbines, is conducted along the shafting from the steam-heated rotors. Removal of this heat by the lube oil prevents serious damage to the machinery parts and makes it necessary to have the oil repeatedly cooled as it circulates about the mechanisms.

In general, BOTH FRICTION AND OPERATING TEMPERATURES in bearings increase with a greater unit bearing pressure; with thinner films of the lubricant, if below a definite minimum; with a high velocity of rubbing or rotation of the journal; and with a higher viscosity of the lubricant. (Viscosity refers to the flowing qualities of a liquid. Water and gasoline, or liquids which flow freely, have a low viscosity. Cold molasses and honey do not flow freely; therefore they have a high viscosity.)

Bearing Lubrication

Most of the moving parts of a machine are supported in bearings that permit them to rotate freely. Lubrication consists of supplying these bearings with oil. The oil forms a film on the surfaces of the shaft and the bearing, and keeps them separated (fig. 7-23). An oil must be selected that has enough body to keep the metal surfaces from touching each other under ALL operating conditions.

Bearings that carry a heavy load are sometimes lubricated with grease. These bearings are equipped with standard grease cups or zerk fittings like those on an automobile. The cups must be kept filled at all times. The shafts of some rotary water pumps are lubricated by permitting a small amount of water to leak through the bearings and moisten the packing.

Lubricating Systems

Each turbine is provided with a lubricating system that supplies oil under pressure to the bearings. The system consists of a sump or reservoir for storing the oil, an oil pump, a strainer, a cooler, temperature and pressure

OIDC

Figure 7-23.—The oil film (exaggerated view) separates the rotating shaft from the bearing.

gages, and the necessary piping to carry the oil to the bearings and back to the sump. The location and arrangement of these parts vary with each make and type of turbine.

The lube oil pump is generally a positive-displacement rotary pump. A definite pressure is maintained in the oil feed lines. A pressure relief valve allows excess oil to recirculate back to the suction side of the pump.

Quite often dual strainers are connected in the line so that the system can operate on one strainer while the other one is being cleaned. The tube-in-shell type of cooler is generally used with sea water circulating through the tubes and the oil flowing around them. The temperature of the oil is controlled by adjusting the valve that regulates the amount of sea water flowing through the tubes.

Oil must circulate through the turbine bearings at the prescribed pressure and within certain temperature limits. A pressure gage installed in the feed line and a thermometer installed in the return line indicate whether the oil system is functioning properly. Thermometers are often installed in the bearings to serve as a warning against overheating. If there is a decided drop in oil pressure, the engine should be shut down immediately; even a moderate rise in the oil temperature should be investigated. An oil-level float gage indicates the amount of oil in the sump.

Lubricating Oil and Greases

Many different kinds of lubricating materials are in use, each of them filling the requirements of a particular set of conditions. Animal and vegetable oils and even water have good lubricating qualities, but they cannot withstand high temperatures. It has been found that mineral oils, similar to the oils used in an automobile engine, are the best type of lubricant for modern machinery operating at high speeds and high temperatures. Some heavy-duty bearings are lubricated with grease in about the same way that the spring shackles and steering gear of your car are greased.

Mineral lubricating oils are derived from crude oil in the same process which produces gasoline, kerosene, and fuel oil. They vary according to the type of crude oil and the refining methods used. The same type of oil is usually made in several grades or weights. These grades correspond to the different weights of oil for an automobile varying from light to heavy.

Oils used in the Navy are divided into 9 classes, or series, depending upon their use. Each type of oil has a symbol number that indicates its class and viscosity. For example, symbol 2190 oil is a number 2 class of oil with a viscosity of 190 Saybolt Seconds Universal. The viscosity number represents the time in seconds that is required for 60 cubic centimeters (cc) of the oil, at a temperature of 130°F, to flow through a standard size opening in a Saybolt viscosimeter (fig. 7-24).

A 2190TEP oil is used for all propulsion turbines and reduction gears. The letters TEP indicate that the oil has been treated to give it water-protecting and corrosion-resisting properties, and extra load carrying capacity. This oil is also used in the turbines that drive the various kinds of pumps and blowers, except those that are driven through a worm gear. These pumps use a Navy sumbol 3080 oil.

Lubricating greases are mixtures of soap and lubricating oil. Fillers, such as graphite, are also added to some greases to make the greases more effective for certain lubrication requirements.

The soaps used in the common SOAP AND OIL GREASES are chemical compounds formed by fats or fatty acids reacting with various alkaline materials such as lime, soda, aluminum, zinc, barium, lithium, lead, and potassium.

9412

Figure 7-24.—Details of the viscosimeter tube.

The common SODA SOAP GREASES are used for applications where no water is present and where operating temperatures approach 200°F. The common LIME SOAP GREASES do not absorb moisture or emulsify as readily as the soda soap greases, but have lower melting points. They are used as general purpose greases for light load applications at ordinary operating temperatures. These two types of greases will satisfactorily lubricate the majority of machinery.

Certain lubricating greases contain additives. These SPECIAL ADDITIVE GREASES are identified by the additive. For example, LEAD OLEATE SOAP GREASES are used for certain bearing surfaces which are so heavily loaded that the ordinary grease will not maintain a film to prevent contact of the rubbing surfaces. EXTREME PRESSURE GREASES also incorporate special additive agents to provide necessary film strength.

OXIDATION INHIBITOR GREASES have an additive incorporated to ensure better stability at high temperatures and to prevent rusting under these conditions. In GRAPHITE GREASES, the added graphite acts as a mild abrasive to help smooth roughened surfaces, and acts as a filler to smooth over unequal surface spots. It also substitutes its own low friction for that of the metal it covers; this is especially important where a bearing is exposed to temperatures so high that ordinary grease or oil would break down. Except for such high temperatures, graphite grease should not be used in bearings which are in first-class condition.

Each of these several types of greases is supplied in three grades: soft, medium, and hard. The SOFT GRADES are used at high speeds under light pressure; the MEDIUM GRADES are used at medium speeds under medium pressure; and the HARD GRADES are used at slow speeds under heavy pressure.

Standard Navy Lubrication

Always be sure that you are using the specified lubricant for the individual machinery part, unit, or system you are responsible for operating or maintaining.

Most ships make up LUBRICATING CHARTS for quick reference on this information. These charts generally contain a line diagram of the unit or system, point of lubrication, symbol of lubricant, quantity, and interval of supply—along with applicable general instructions, operating hints, and possible casualties. The charts are generally posted in machinery compartments.

The manufacturer's technical manual for each unit of machinery is the basic reference for the correct lube oil, if no lubrication chart (based on manufacturer's instructions) is available. In addition, the TABLE OF RECOMMENDED OILS can be found in chapter 9450 (45) of BuShips Technical Manual.

9413

CHAPTER 8

AUXILIARY MACHINERY AND EQUIPMENT

In addition to the propulsion machinery and equipment you will become acquainted with a number of other units of machinery. These include refrigeration equipment, air conditioning equipment, and distilling plants. You will also become acquainted with the steering gear, the anchor windlass and capstan, lube oil purifiers, laundry equipment, galley equipment, air compressors, cranes, elevators and winches. The information provided in this chapter will be general in nature and will deal primarily with the location and the function of the auxiliary machinery and equipment mentioned.

REFRIGERATION EQUIPMENT

There are two basic types of mechanical refrigeration systems used in the Navy; the steam-jet refrigeration system and the vapor compression refrigeration system. The steam-jet system is used on some naval ships for air conditioning and on some merchant type ships for large area, moderate temperature refrigeration. The vapor compression system, which is the most common, may be adapted for use on naval ships in various applications including refrigerated ship's stores, refrigerated cargo, and unitary (self contained) refrigeration (as ship's service store equipment).

Ship's stores spaces are refrigerated for the preservation of food supplies. The insulated compartments for cold storage spaces are of the walk-in type. The equipment selected for cooling these spaces is designed to maintain certain temperatures: on ships designed before 1950, the meat room at 15°F, fruit and vegetable rooms at 40°F, butter and egg rooms at 32°F; and for ships designed since 1950, the freeze room at 0°F and the chill room at 33°F.

Refrigerated cargo spaces are provided on auxiliary ships for the stowage of perishable food that is intended for the forces afloat and advanced bases. The temperatures of the refrigerated cargo spaces are such that approximately 30 to 60 percent of the total refrigerated area is maintained at a temperature of 0°F (-5°F for latest design ships). The remainder of the refrigerated area is maintained at a temperature of 33°F to 35°F.

Unitary refrigeration systems are of two types—remote and self-contained. The remote type is a complete unit except that the source of refrigeration is located separately and is not contained within the unit cabinet. Equipment of this type includes soda fountains and ice cream hardening machines.

The self-contained units, which have the refrigeration source within the unit cabinet, include drinking water coolers, refrigerators, and frozen food cabinets.

Other refrigeration equipment includes two types of ice-making machines. One type is a self-contained unit and makes ice cubes. The other is the tank type and makes large slabs of ice. The tank type of ice machine is normally located in a separate machinery room which is identified as the ice machine room. This type has been installed on auxiliary ships such as tenders and repair ships.

AIR CONDITIONING EQUIPMENT

Air conditioning is installed on naval ships for certain spaces where personnel efficiency, health, safety, or operation of equipment could be endangered by high temperatures or high humidity.

There are two basic types of air conditioning equipment used aboard ship. One type uses chilled water for the cooling medium; the other uses a refrigerant, R-12 to carry away the heat. Most of the air conditioning equipment used aboard Navy ships uses the refrigeration equipment for the removal of heat from the circulating water or refrigerant. The removal of the heat is accomplished by the cooling coils of the refrigeration equipment. There are also some smaller self-contained units used aboard ship, like the ordinary window type used in homes.

9414

Some of the spaces that might be air conditioned include the radio and radar control spaces, sick-bay areas, and living and berthing spaces. The radio and radar control spaces are usually air conditioned because of the high heat given off by the equipment. This heat, especially in combination with high humidity, could be dangerous to the operator and the equipment. Air conditioned sick-bay areas have proved advantageous in that they help to speed recovery. The living and berthing spaces are often air conditioned, both to provide comfort for the crew and because air conditioning helps to increase personnel efficiency.

DISTILLING PLANTS

The two basic types of distilling plants installed on naval ships are the vapor compression distilling plant and the steam distilling plant. The main difference between the two types of distilling plants comes from the method used for applying heat to the sea water. In the vapor compression plant, the source of heat is obtained from electrical energy.

The vapor compression type distilling plant was first developed primarily for submarine service, where the absence of steam made it necessary to supply another form of heat energy. This type of plant is currently used on small diesel-driven ships and on ships where the daily demand for fresh water is less than 4,000 gallons per day (gpd). The vapor compression plant consists of three main components, the evaporator, the compressor, and the heat exchanger.

Steam operated distilling plants are classified as coil, submerged tube, vertical basket, and flash types. The coil type is found on a few older auxiliaries; while the submerged tube type is found on most older ships. The vertical basket and flash types are newer designs, and have been installed on some combatant ships constructed in the last 10 years. Some submerged tube types have also been installed during this period.

In the vertical basket type, low pressure steam flows into a corrugated basket that is surrounded by sea water. Here the steam gives up its heat to boil the sea water and is then condensed. The fresh water vapor from the boiling sea water is condensed and then removed as distillate (fresh water).

In the flash type, preheated feed water is discharged into a vacuum chamber where a portion of the water vaporizes (flashes into steam). The remaining water passes into a second flash chamber where further vaporization takes place. Any number of flash chambers, where vaporization takes place, can be installed. Each stage has a condenser in which the fresh water vapor is condensed.

There are three basic types of submerged-tube type distilling plants: soloshell double-effect (fig. 8-1), the triple-effect, and the two-shell double-effect. The principal difference between the triple-effect plant and the two-shell double-effect plant is the number of stages of evaporation. In the double-effect plant evaporation takes place in two stages while in the triple-effect plant evaporation takes place in three stages.

The most commonly used 20,000 gpd two-shell double-effect plant is built with two horizontal cylinder evaporator shells mounted parallel to each other. The triple-effect distilling plant is similar to the two-shell double-effect plant except that the triple-effect plant has an intermediate evaporating stage. A standard triple-effect, 20,000 gpd plant is illustrated in figure 8-2.

Almost all low pressure distilling plants up to and including the 12,000 gpd capacity plant are of the soloshell double-effect type. This type consists of a single shell that is designed with a vertical partition which divides the shell into two evaporator shells.

One type of 20,000 gpd capacity, soloshell double-effect plant was installed on light and heavy cruisers. Where it was necessary to furnish 40,000 gpd, two such plants were installed. Some older destroyers (2200 ton) are equipped with two soloshell evaporator plants—one, located in the forward engineroom, has a capacity of approximately 12,000 gpd; while the other, in the aft engineroom, has a capacity of approximately 4,000 gpd. The 2100 ton destroyers have only one 12,000 gpd plant; it is located in the forward engineroom.

STEERING GEARS

There are three basic types of steering mechanisms in use in the Navy. The first type is the steam steering gear, used only on a few naval auxiliary ships. The second type is the electromechanical type, used extensively on small noncombatant ships. The third and most common type is the electrohydraulic steering gear.

The steam steering gear consists of a pair of reversible, reciprocating steam engines which

9415

Figure 8-4.—Diagrammatic arrangement of a double-ram electrohydraulic steering gear.

47.139X

drive a geared quadrant which is attached to the rudder stock. (See fig. 8-3) Emergency steering for this type is accomplished by attaching wire ropes to a hand winch.

Electromechanical steering gear includes the steam steering gear plus an electric motor. The electric motors on steam steering gears were first introduced to provide for emergency steering in the event of steam failure. Later the electric motor became the prime mover and the steam steering system was kept in reserve for emergency use.

With the electrohydraulic type of steering gear, movement of the rudder is obtained from hydraulic rams operating in cylinders that are connected to variable delivery pumps. The development of this type was prompted by the large electrical power requirement necessary to steer ships of large displacement and high speeds.

The electrohydraulic steering gear provided some distinct advantages over the steam and the electromechanical types of steering gears. These advantages include: (1) little friction between moving parts, (2) immediate responses to movement of the steering wheel, (3) requires small deck space and head room, (4) savings in weight, and (5) flexibility and dependability.

There are various types of electrohydraulic steering gears in use, but their operating principles are basically the same. Some ships have double hydraulic rams and cylinders mounted fore and aft, as shown in figure 8-4; while other ships employ a double cylinder, single-ram, mounted athwartships. A typical single-ram electrohydraulic steering gear is illustrated in figure 8-5.

Emergency steering gear is provided on all combatant and auxiliary naval ships having electrohydraulic steering gear. Large combatant ships generally have a duplicate hydraulic steering gear for emergency use. On other ships the emergency gear consists of a hand-operated hydraulic pump.

ANCHOR WINDLASSES AND CAPSTANS

The term windlass refers to a piece of deck machinery used primarily for paying-out and heaving-in on anchor chain. A wildcat (drum), fitted with whelps to engage the anchor chain may be mounted vertically or horizontally at the end of the windlass shaft. (A whelp is any one of the ribs or ridges on the drum of a windlass. It looks much like the sprocket wheel of a chain fall.)

Figure 8-5.—Diagram of typical single-ram electrohydraulic steering gear system. 27.83X

Figure 8-6.—Typical electrohydraulic anchor windlass arrangement.

General requirements of the anchor windlass are that it must be simple, rugged, and reliable. It must be capable of reversal and have suitable brakes.

There are three general types of power-driven anchor windlasses: electrohydraulic, electric, and steam. Hand-operated windlasses are used on small ships where the weight of the anchor gear is such that it can be handled without excessive effort by operating personnel.

The electrohydraulic anchor windlasses are advantageous where the load varies through a wide range because of the amount of anchor chain payed out, the force of the wind, the strength of the tide, and the type of bottom in which the anchor is set. Figure 8-6 illustrates a typical electrohydraulic anchor windlass arrangement.

Some older naval ships, such as cruisers, were equipped with geared windlasses driven by a steam engine or an electric motor. Some of the new smaller combatant ships such as destroyers and destroyer escorts are equipped with the electric motor type. Figure 8-7 illustrates an electric windlass of a modern destroyer.

A capstan is a spool shaped, vertically mounted drum used for heaving in on heavy mooring lines. Figure 8-8 shows a vertical shaft anchor windlass capstan which is normal topside equipment on a destroyer. The capstan is a component part of the anchor windlass, as shown in figures 8-6 and figure 8-7.

LUBE OIL PURIFIERS

Purifiers, which are normally located in the engineroom, are used to free contaminated lube oil or diesel oil of water, sediment and other impurities. The purifiers used in the naval service operate on the principle of centrifugal force; that is, a bowl or hollow cylinder is revolved at high speeds while contaminated oil is passed through it. This procedure separates the impurities from the oil. Purifiers are divided into two classifications, the tubular type and the disk type.

The hollow cylinder or tubular type is of relatively small diameter and is operated at high speed. The cylinder is fitted with a device known as a three-wing, that functions to keep the liquid

Figure 8-7.—Electric windlass. 3.224X

rotating at the speed of the bowl without slippage. Figure 8-9 shows the tubular type of purifier.

The disk type purifier is characterized by a larger diameter bowl, which is fitted with a series of disks that separate the liquid into thin layers. A sectional view of a disk type purifier is shown in figure 8-10.

AIR COMPRESSORS

There are many uses for compressed air aboard ship and it would be difficult to mention all of them. Some of the more common uses include: operating pneumatic tools, ejecting gas from ship's guns, starting diesel engines, charging and firing torpedos, operating gun counterrecoil mechanisms, and operating automatic combustion control systems. Compressed air is supplied to the various systems by high pressure, medium pressure, or low pressure air compressors, as appropriate. Reducing valves reduce a higher pressure to a lower pressure for a specific system. Air compressors are classified in a number of ways. A compressor may be single-acting (compression on one end of the stroke), double-acting (compression on each end of the stroke), single stage (one cylinder),

Figure 8-8.—Vertical shaft anchor windlass capstan head. 47.146

Figure 8-9.—Tubular type centrifugal purifier (Sharples).

47.86

multistage (more than one cylinder) and the compressor design may be such that the pistons operate horizontally, vertically, or at an angle. Compressors are also classified according to the type of compressing element, the source of driving power, the method by which the driving unit is connected to the compressor, and the pressure that is developed.

Air compressors may be of the centrifugal, rotary, or reciprocating types. The type used is determined by the volume and pressure of air desired. Most of the compressors used in the Navy are of the reciprocating type.

Compressors are driven by electric motors, internal combustion engines, steam turbines, or reciprocating steam engines. The air compressors used most in the Navy are driven by electric motors.

Low pressure compressors are those which have a discharge pressure of 150 psi or less. Medium pressure compressors are those which have a discharge pressure of 151 psi to 1000

Figure 8-10.—Disk type centrifugal purifier.

psi. Compressors which have a discharge pressure above 1000 psi are classified as high pressure air compressors.

CRANES

Cranes are designed for raising a load, lowering it, and moving it in horizontal directions. You will find cranes installed on carriers, cruisers, and auxiliaries. Cranes are used for handling airplanes, boats, bombs, torpedoes, mines, sweep gear, missiles, trucks, and stores. Some submarines are also equipped with cranes for handling missiles.

In general, cranes may be electrically driven, engine driven, or hand driven. Cranes constructed for very heavy loads (lifting heavy aircraft, boats, or missiles) are usually electrohydraulic.

Detailed information concerning shipboard cranes can be obtained from applicable manufacturers' technical manuals.

ELEVATORS

Many Navy ships are equipped with elevators which are used to handle bombs, airplanes, freight, torpedoes, and ammunition. Shipboard elevators may be divided into two general classes: electrohydraulic and electromechanical elevators.

ELECTROHYDRAULIC elevators may be divided into two general types: the direct plunger lift and the plunger-actuated cable lift.

The platform of the DIRECT PLUNGER LIFT elevator is raised or lowered by one or more hydraulic rams, which are located under the platform. During the hoisting of a platform, hydraulic oil is pumped into the ram from a high pressure tank (approximately 950 psi). Lowering of the platform is performed by discharging the oil from the rams into a low pressure tank, which is under an approximate pressure of 230 psi.

9422

6580

Figure 8-11.—Units of an electromechanical winch.

80.149

Pressure is maintained in the high pressure tank by means of two hydraulic pumps (variable stroke), which take suction from the low pressure tanks. Special control valves, located in the pressure and exhaust lines, regulate elevator speeds by varying the amount of hydraulic oil admitted to, or discharged from the rams. Mechanical locks allow the platform to be locked and held in position at deck level. Automatic quick-closing valves in the oil line prevent an unrestricted fall of the elevator.

The platform of the PLUNGER-ACTUATED CABLE LIFT elevator is raised by wire rope fastened to the platform at either two or four points. Most hydraulic airplane elevators are of this type. The wire ropes in an airplane elevator are operated through a series of pulleys, by a horizontal hydraulic ram located below the hangar deck. Special safety devices, provided to engage the guide rails of the elevators, stop the fall and hold the platform when one group of wire ropes fails.

ELECTROMECHANICAL elevators are used for freight, bombs, and stores. In elevators of this type, the platform is raised and lowered by one or more wire ropes which pass over pulleys and wind or unwind on hoisting drums. Hoisting drums are driven through a reduction gear unit by an electric motor. An electric brake is provided to stop and hold the platform. The motor has two speeds (full speed and low, or one-sixth speed). Control arrangements are such that the elevator starts and runs on high speed. Low speed is used for automatic deceleration as the elevator approaches the selected level. The platform travels on two or four guides. Hand-operated

9423

CHAPTER 9

INSTRUMENTS

Measurement is, in a very real sense, the language of engineers. The shipboard engineering plant has many instruments that indicate, to operating personnel, conditions existing within a piece of machinery or a system. By proper interpretation of the readings of the instruments, operating personnel can determine if the machinery, or the system, is operating within the prescribed range.

Recorded instrument readings are used as a means of ensuring proper operating procedures and also for determining the operating efficiency of the plant. The instruments provide information for the hourly, daily, and weekly entries for operating records and reports. The data entered in the records and reports must be accurate since the engineer officer studies the records and reports to keep up with the condition of the plant. Remember that accurate data entered on the records and reports can only be obtained by reading the instruments carefully.

The instruments, indicators, and alarms discussed in this chapter are included not only because of the relative importance in the engineering plant; but also to give you an idea of the wide range and type of instruments, indicators, and alarms that are used in the engineering plant aboard a naval ship.

Engineering measuring instruments may be classified into the following five groups:

1. Pressure gages.
2. Thermometers and pyrometers.
3. Liquid level indicators.
4. Fluid flow meters.
5. Revolution counters and indicators.

PRESSURE GAGES

Pressure gages include a variety of Bourdon tube gages, bellows and diaphragm gages, and manometers. The Bourdon tube gages are generally used for measuring pressure of 15 pounds per square inch (psi) and above. The bellows and diaphragm gages and manometers are generally used for measuring pressures below 15 psi.

BOURDON TUBE GAGES

The most common Bourdon tube gages used in the Navy include (1) simplex, (2) vacuum, (3) compound, and (4) duplex gages. They operate on the principle that pressure in a curved tube will have a tendency to straighten out the tube. The tube is made of bronze for pressures under 200 psi, and of steel for pressures over 200 psi. Figure 9-1 shows a Bourdon tube installed in a gage case.

The Bourdon tube is in the shape of a C and is welded or silver-brazed to the stationary base. The free end of the tube is connected to the indicating mechanism by a linkage assembly. The threaded socket, welded to the stationary base, is the pressure connection. When pressure enters the Bourdon tube, the tube straightens out slightly and moves the link connected with the toothed gear sector. The teeth on the gear sector mesh with a small gear on the pinion to which the pointer is attached. Thus when pressure in the tube increases, the gear mechanism pulls the pointer around the dial and registers the amount of pressure being exerted in the tube.

The simplex gage, shown in figure 9-2, may be used for measuring the pressure of steam, air, water, oil, and similar fluids or gases.

The Bourdon tube vacuum gage commonly used for indicating vacuum, in inches of mercury, on auxiliary condensers, is illustrated in figure 9-3. Vacuum gages indicate pressure below atmospheric pressure whereas pressure gages indicate pressure above atmospheric pressure.

The compound Bourdon tube gage (fig. 9-4) uses a single Bourdon tube of such great elasticity that it can measure vacuum to the left of the zero point and pressure to the right of the zero point. When the pointer is to the right of

9425

38.211X

Figure 9-3.—Bourdon tube vacuum gage.

38.211X

Figure 9-4.—Compound Bourdon tube gage.

the zero point, it measures pressure in pounds per square inch (psi).

The duplex Bourdon tube gage illustrated in figure 9-5 has two separate gear mechanisms within the same case. A pointer is connected to the gear mechanism of each tube. Each pointer operates independently of the other pointer. Duplex gages are commonly used for such purposes as showing the pressure drop between the inlet side and the outlet side of lube oil strainers. If the pressure reading for the inlet side of the strainer is much greater than the pressure reading for the outlet side, it is very likely that the strainer is very dirty, and is thus restricting the flow of lube oil through the strainer.

BELLOWS GAGES

A bellows gage is generally used to measure pressures below 15 psi. Some types are satisfactory for measuring draft pressures and for general low pressure measurements. The bellows of the gage is made of stainless steel, brass, beryllium-copper, Monel, or phosphor bronze. A bellows is shown in a gage case in figure 9-6.

When pressure in the line to a bellows gage increases, the bellows increases in length and operates a system of gears and levers which are connected to the pointer. The pointer then registers the higher reading on the dial. When the pressure to the bellows gage decreases, the bellows returns to its normal length, returning the pointer toward zero. When the pressure to the bellows is completely removed, the hairspring of the pointer returns it all the way back to zero.

DIAPHRAGM GAGES

Diaphragm gages are sensitive and give reliable indications of small differences in pressure. Diaphragm gages are generally used to measure air pressure in the space between the inner and outer boiler casings.

The indicating mechanism of a diaphragm gage, shown in figure 9-7, consists of a tough, pliable, neoprene rubber membrane connected to a metal spring which is attached by a simple linkage system to the gage pointer.

One side of the diaphragm is exposed to the pressure being measured, while the other side is exposed to the atmosphere. When pressure is applied to the diaphragm, it moves upward and pushes the metal spring ahead. As the spring is pushed up, it moves the pointer, connected to it with a chain, to a higher reading on the dial. When the pressure is lowered the diaphragm pulls the pointer back toward the zero point.

MANOMETERS

A manometer is perhaps the most accurate, least expensive, and simplest instrument for measuring low pressure, or low pressure differentials. A manometer, in its simplest form consists of a glass U-tube of uniform diameter, filled with a liquid. The most common liquids used are water, oil, and mercury. One end of the U-tube is open to the atmosphere and the other end is connected with the pressure to be measured.

Manometers are available in many different sizes and designs. They all operate on the same principle. Two common types of manometers are shown in figure 9-8.

THERMOMETERS AND PYROMETERS

A thermometer is an instrument which measures temperature. The temperature measured may be that of steam to the main engines, brine in an ice machine, oil and bearings in the main engines, or substances in many other locations. In general a thermometer measures changes in temperature by utilizing the effect of heat on the expansion of a liquid or a gas.

Thermometers are designed as (1) direct reading, liquid-in-glass type, (2) bimetallic type, or (3) distant reading, indicating dial type thermometers.

LIQUID-IN-GLASS THERMOMETERS

Liquid-in-glass thermometers are filled with mercury, ethyl alcohol, benzine, water, or some other liquid suitable for the temperature range involved. Most of the liquid-in-glass thermometers used in the engineering spaces are filled with mercury. When a thermometer is exposed to a temperature to be measured, heat causes the liquid in the bulb to expand and rise in the glass stem. Cold, or the absence of heat, causes the liquid to contract.

Liquid-in-glass thermometers are designed so that the face will be in the best position for reading when the thermometer is installed. Some thermometers with different angles are shown in figure 9-9.

9428

Figure 9-9.—Thermometers with angle sockets.

BIMETALLIC DIAL THERMOMETERS

Bimetallic dial thermometers use a bimetal element for indicating temperature changes on a circular dial. The bimetallic actuator is a single-helix coil fitted closely to the inside of the stem tube. A rise in temperature causes the actuating element to expand. Because the element is composed of two thin strips of different metals with each metal having a different rate of expansion, the element expands by unwinding instead of by expanding against the sides of the tube. The pointer shaft is secured to the free end of the element and thus registers the amount of element

9429

61.28X

Figure 9-11.—Distant reading dial thermometer.

movement on the dial face. Figure 9-10 shows the actuating element of a bimetallic thermometer.

DISTANT READING DIAL THERMOMETERS

Distant reading dial thermometers are used when indicating portions of the instrument must be placed at a distance from where the temperature is being measured. The mercury filled, distant reading thermometer, shown in figure 9-11, is the most common type used aboard ship. There are other types, but they are not commonly used aboard ship and will not be discussed.

The mercury filled, distant reading thermometer (fig. 9-11) consists of a mercury bulb, capillary tubing, and a Bourdon tube pressure gage. The mercury bulb, the capillary tubing, and the Bourdon tube in the pressure gage are all filled with mercury.

The mercury bulb is the sensing element. It is inserted and fastened securely (either threaded or bolted) in an opening in a pipe or turbine pump casing, for instance, where a temperature measurement is desired.

The capillary tubing is constructed similar to armored electric cable, but instead of having wires or cables inside, the armor contains a small flexible metal tube. The capillary tubing must be handled carefully and must be maintained free of kinks and twists, so as not to disrupt the mercury column within the tubing.

The Bourdon tube pressure gage was discussed earlier in this chapter. The gage contains a Bourdon tube which has a tendency to

61.34X

Figure 9-12.—Diagrammatic arrangement of a thermocouple.

61.5X

Figure 9-13.—Static head gaging system.

9430

straighten out, as the pressure in the Bourdon tube increases.

Putting the three major units of the distant reading thermometer (mercury bulb, capillary tubing) and the pressure gage) together, let us see what happens. Remember that all three of these units are filled with mercury. Now when the temperature rises, the increase causes the mercury in the bulb to expand. The expansion of the mercury in the bulb causes a pressure to be built up in the capillary tubing. This same pressure is transmitted through the capillary tubing into the Bourdon tube in the pressure gage. The Bourdon tube straightens out and, through an assembly of gears and levers, causes a pointer to move around a dial, which has previously been calibrated to show corresponding temperatures. The expansion of the mercury in the bulb results in a movement of the pointer that is directly proportional to the temperature applied to the bulb.

PYROMETERS

Pyrometers are used for measuring temperatures through a wide range, generally between -300°F and 3,000°F. They are used aboard ship to measure temperatures in heat treatment furnaces and exhaust temperatures of diesel engines, and for other similar purposes.

The pyrometer includes a thermocouple and a meter. The thermocouple, made of two dissimilar metals joined together at one end, produces an electric current when heat is applied at its joined end. The meter, calibrated in degrees, indicates the temperature at the thermocouple. Figure 9-12

Figure 9-14.—Boiler gage glass installed on a boiler.

139.32

illustrates the operating principle of the thermocouple of the pyrometer.

LIQUID LEVEL INDICATORS

In the engineering plant, aboard ship, it is frequently necessary for operating personnel to know the level of various liquids in various locations. The level of the water in the ship's boilers is an example of a liquid level that must be known at all times. Other liquid levels that must be known are the level of the fuel oil in storage tanks and service tanks, the level of the water in the deaerating feed tank, and the level of the lubricating oil in the oil sumps and reservoirs of pumps and other auxiliary machinery.

Liquid level indicators, other than sounding rods and tapes, have been constructed in various designs and sizes; some are simple and some are relatively complex. Some indicators measure liquid level directly by measuring the height of a column of liquid.

TANK GAGING SYSTEM

One of the more complex liquid level indicators is shown in figure 9-13. This type of indicator or system is generally used for measuring the liquid level in fuel oil storage tanks aboard ship. It is called a static head gaging system; it balances a head of liquid in the tank against a column of liquid in a manometer. In this system a mercury manometer is used. The balance chamber is located so that its orifice (opening) is near the bottom of the tank; a line connects the top of the balance chamber to the mercury filled bulb of the indicator gage, and another line connects the space above the mercury column to the top of the tank. Since the height of the liquid in the tank has a definite relationship to the pressure exerted by the liquid, the scale can be calibrated to show the height (or liquid level). When the height of the liquid in the tank is known, the measurement of height can be readily converted to volume (gallons).

GAGE GLASSES

The gage glass is one of the simplest kinds of liquid level indicators. Gage glasses are used on boilers, on deaerating feed tanks, on inspection tanks, and on other shipboard machinery. Gage glasses vary in design and construction depending upon pressure or other service conditions.

The liquid level in the gage glass is the same as the liquid level in the container; and the liquid level can be determined by visual observation. A typical boiler gage glass installed on a boiler is shown in figure 9-14.

In addition to the gage glasses, some boilers have been equipped with remote water level indicators. The remote water level indicators are generally installed on the operating level of the boilers to provide the petty officer in charge with a readily obtainable reading of the water level in the steam drum of the boilers. Figure 9-15 illustrates one type of remote water level indicator.

FLUID METERS

Fluid meters are used on board ship to measure the flow rate of fuel oil, diesel oil, water, gasoline, and other liquids. Accurate measurement of the rate of flow of a liquid through a meter is not meaningful unless the recorded amount is correctly read. Some different types of dials used on fluid meters are shown in figures 9-16 and 9-17. The dial readings are generally in U.S. gallons unless otherwise specified on the dial face. The dial faces shown in figure 9-16 are for the straight reading type meter; the dial faces shown in figure 9-17 are for a round reading meter.

139.33

Figure 9-15.—Remote water level indicator.

9432

61.13X

Figure 9-16.—Straight reading registers.

To read the straight reading meter, read from left to right and add the number indicated by the small pointer above. For example in part A of figure 9-16 the reading is 0000280. Part B shows the reading to be 0000285. As the pointer turns, so does the right-hand, numbered roller. Even though the next higher number is partly exposed always read the lesser number, which is the number disappearing from sight. When the small pointer is at 0 all the numbers in the straight reading dial will be centrally aligned, as shown in part A and part G of figure 9-16. When the small pointer is at 8 or 9 (part C of fig. 9-16), the next larger number on the numbered roller is almost completely exposed, but the lesser number must be read. The dial in part C of figure 9-16 reads 288 gallons, not 298 gallons.

61.13X

Figure 9-17.—Round reading registers.

To read the round reading dial face (fig. 9-17) take the lesser number of the two between which the hand points in each circle. Notice that each circle indicates tens, hundreds, thousands, tens of thousands, etc. Place the number taken from the circle marked "tens" in the units position, place the number taken from the circle marked "hundreds" in the tens place; and continue similarly for the remaining circles. Each division of any circle stands for one-tenth of the whole number indicated by that circle. If a hand is on or near a number, read that number instead of the next lower number when the hand in the next lower circle is on or past 0.

REVOLUTION COUNTERS AND INDICATORS

Measurements of rotational speed are necessary for the operation of the pumps, forced

7.143

Figure 9-18.—Revolution counter.

9433

SCAC

38.111X

Figure 9-19.—Permanently mounted centrifugal type tachometer on a forced draft blower.

draft blowers, main engines, and other machinery or equipment of the engineering plant. As a result, various instruments are used to indicate the shaft speed or to count the total number of turns a shaft makes. One type of instrument, the revolution counter, which is mounted on the throttleboard in the engineroom, counts the total number of turns that are made by a main propulsion shaft. These counters are similar to the speedometer of an automobile. A typical revolution counter is shown in figure 9-18.

The most common instrument used in the engineering plant aboard ship, for the measurement of rotational speed, is the tachometer. For most shipboard machinery, rotational speed is expressed in revolutions per minute (rpm). The tachometers generally used aboard ship are of three main types: the centrifugal type, the chronometric type, and the resonant type.

The CENTRIFUGAL tachometer may be either portable (single and multiple range) or permanently mounted. The portable multi-range tachometer has three ranges: low (50 to 500 rpm), medium (500 to 5,000 rpm), and high (5,000 to 50,000 rpm).

Normally, permanently mounted centrifugal tachometers operate off the governor or speed limiting assembly. The tachometer continuously records the actual rotational speed of the machinery shaft. A permanently mounted centrifugal tachometer is illustrated in figure 9-19.

A portable centrifugal tachometer has a small shaft protruding from its case, which is applied manually to a depression or projection on the end of a rotating shaft of a pump, motor, or other machinery. The rotating movement of the machinery shaft is converted to instantaneous values of speed on the dial face of the tachometer. Figure 9-20 shows a portable multi-range centrifugal tachometer.

The portable CHRONOMETRIC tachometer, shown in figure 9-21, is a combination watch and revolution counter. It measures the average number of revolutions per minute of a motor shaft, pump shaft, etc. The mechanism of this tachometer is such that its outer drive shaft runs free when applied to a rotating shaft, until a starting button is depressed to start the timing element. Note the starting button beneath the index finger in figure 9-21. The chronometric tachometer retains readings on its dial after its

Figure 9-20.—Multi-range centrifugal tachometer. 61.17X

9435

2.66X

Figure 9-21.—Portable chronometric tachometer.

61.16X

Figure 9-22.—Mounted resonant reed tachometer.

drive shaft has been disengaged from a rotating shaft, until the pointers are returned to zero by the reset button (usually the starting button). The range of a chronometric tachometer is usually from 0 to 10,000 rpm, and from 0 to 3,000 feet per minute (fpm).

Each portable centrifugal or chronometric tachometer is supplied with a small rubber covered wheel and a number of hard rubber tips. The appropriate tip or wheel is fitted on the end of the tachometer drive shaft, and held against the shaft to be measured. Portable tachometers of the centrifugal or chronometric type are used for intermittent readings only, and are not used for continuous operation.

The RESONANT REED tachometer, illustrated in figure 9-22, is particularly useful for measuring high rotational speeds such as those that occur in turbines and generators. This type of tachometer is particularly suitable where it is practically impossible to reach the moving ends of the machinery shafts. This instrument gives continuous readings and is capable of making very rapid, instantaneous adjustments to rotational speed.

Resonance is the quality of an elastic body which causes it to vibrate vigorously when subjected to small, rhythmic impulses at a rate equal to its natural frequency, or nearly so. In a resonant reed tachometer, resonance provides a simple but accurate means for measuring speed and rate of vibration.

A resonant reed tachometer consists of a set of consecutively tuned steel reeds mounted in a case with a scale to indicate rpm of the shaft and vibrations per minute (vpm) of the reeds. This tachometer has no pointer—only a set of accurately tuned reeds— and it operates without direct contact with a moving part under test. It has no gears or couplings, and it requires no oiling and practically no maintenance.

OTHER ENGINEERING INSTRUMENTS

There are a great number of additional instruments and indicators used in the engineering plant. This section attempts to acquaint you with those additional instruments that you most likely will be seeing or working with in the engineering department. These additional instruments include superheater temperature alarms, superheater steam flow indicators, smoke indicators, salinity indicators, lube oil pressure alarms, engine order telegraph, and many others.

SUPERHEATER TEMPERATURE ALARMS

Superheater temperature alarms are installed on most boilers to warn operating personnel of

61.31X

Figure 9-23.—Superheater temperature alarm.

dangerously high temperatures in the superheater of the boilers. Some superheater temperature alarms operate similarly to the Bourdon tube pressure gage. As heat is applied, the mercury in the spiral wound Bourdon tube expands, causing the Bourdon tube to move a cantilever arm toward an electric microswitch. As the preset alarm temperature is reached, the cantilever arm engages the microswitch, setting off a warning howl or buzzer. The warning signal continues until the superheater temperature has been lowered to about 10° or 15°F below the preset alarm temperature. The signal or alarm stops because the mercury in the Bourdon tube contracts, moving the Bourdon tube, which in turn causes the cantilever arm to move away from the microswitch, shutting off the alarm. A diagrammatic arrangement of one type of superheater alarm is shown in figure 9-23.

STEAM FLOW INDICATOR

Steam flow indicators are used to show the rate of flow of steam through the superheater

38.60

Figure 9-24.—Smoke indicator.

of double-furnace boilers. Before fires are lighted in the superheated side of double-furnace boilers, the operator must ensure that a sufficient flow of steam is passing through the superheater. The flow of steam is necessary to carry off the heat of combustion in the superheated side of double-furnace boilers in order to prevent overheating of the superheater tubes, drums, and headers.

The steam flow indicator is calibrated in inches and is normally set at 2 inches as the minimum low. In other words, fires should not be lighted in the superheated side of double-furnace boilers until the pointer on the steam flow indicator has reached the 2-inch mark, which is an indication of sufficient flow of steam.

SMOKE INDICATOR

Smoke indicators (periscope type) are used to provide the boiler operator with visual indications of conditions in the stack above the furnace area. A smoke indicator is shown in figure 9-24.

Figure 9-26.—Engine order telegraph. 139.49

Figure 9-25.—Salinity cell and valve assembly. 7.150

SALINITY INDICATOR

Electrical salinity indicating cells (fig. 9-25) are installed throughout distilling plants to maintain a constant check on the distilled water. An electrical salinity indicator consists of a number of salinity cells in various locations in the plant; for example, in the evaporators, condensate pump discharge, and the air-ejector condenser drain. These salinity cells are all connected to a salinity indicator panel.

Since the electrical resistance of a solution varies according to the amount of ionized salts in solution, it is possible to measure salinity by measuring the electrical resistance. The salinity indicator panel is equipped with a meter calibrated to read directly in either equivalents per million (epm) or in grains per gallon (gpg). The newer type salinity indicators are calibrated in epm.

LUBE OIL PRESSURE ALARM

Lube oil pressure alarms are installed on all generators and main propulsion engines to provide the operator with a signal indicating that the lube oil pressure to the bearings is dangerously low. Low lube oil pressure could cause a number of casualties that would impair the operating condition of the machinery involved. The lube oil pressure alarm, which is either a rapidly ringing bell or loud siren, receives its signal from the bearing that is the most remote from the lube oil pump. When the alarm is sounded the affected machinery must be stopped immediately, the cause determined, and corrective measures taken.

ENGINE ORDER TELEGRAPH

The engine order telegraph (speed indicator), shown in figure 9-26, relays the speed, requested by the officer of the deck while underway, to the throttleman in the engineroom. The engine order telegraph is generally mounted on the throttleboard adjacent to the throttle valves, so that it is readily visible to the throttleman. The following table lists speed changes which may be indicated via the engine order telegraph.

AHEAD	STOP	ASTERN
1/3		1/3
2/3		2/3
I - Standard		Full
II - Full		
III - Flank		

The wrong direction alarm is connected to the engine order telegraph and the main engine throttle valves. If the engine order telegraph indicates "ahead" and the throttleman attempts to open the astern throttle valve, a loud signal or alarm is sounded.

CHAPTER 10

PUMPS, VALVES, AND PIPING

As a Fireman, you should have a general knowledge of the basic operating principles of the various types of pumps used by the Navy. Pumps are used to move any substance which flows or which can be made to flow. When thinking of the term pumping, you probably think of moving water, oil, air, steam, and other common liquids and gases. Substances such as molten metal, sludge, and mud are also fluid and can be pumped with specially designed pumps.

A pump is essentially a device which uses an external source of power to apply a force to a fluid in order to move the fluid from one place to another. A pump transforms energy from the external source (such as an electric motor or steam turbine) into mechanical kinetic energy, which is revealed by the motion of the fluid. This kinetic energy is then used to do work: to raise a liquid from one level to another, as when lifting water from a well; to transport a liquid through a pipe, as in an oil pipeline; to move a liquid against some resistance, as when filling a boiler under pressure; or to force a liquid through a hydraulic system against various resistance.

Aboard ship, pumps are used for a number of essential services. Pumps supply water to the boilers, draw condensate from the condensers, supply sea water to the fireman, circulate cooling water for coolers and condensers, pump out bilges, transfer fuel oil, supply sea water to the distilling plants, and serve many other purposes. The operation of the ship's propulsion plant and of almost all the auxiliary machinery depends upon the proper operation of pumps. Pump failure may cause failure of an entire power plant.

If a system has a pump, it must also contain devices for controlling the volume of flow, the direction of flow, or the operating pressure of the system. A device that performs one or more of these control functions is called a VALVE.

In addition to pumps and valves, this chapter will discuss piping which is a vital part of the ship's engineering plant.

PUMPS

Pumps are classified in accordance with design and operational features. Pumps may be classified, according to the type of movement that causes the pumping action (reciprocating, rotary, centrifugal, propeller, or jet pumps). Pumps are also classified by the rate of speed, the rate of discharge, and the method of priming. Some pumps run at variable speed; others at constant speed. Some pumps have a variable capacity; others discharge at a constant rate. Some pumps are self-priming; others require a positive pressure on the suction (intake) side before they can begin to move a liquid.

Regardless of classification, a pump must have a POWER END and a FLUID END. The power end may be a steam turbine, a reciprocating steam engine, a steam jet, or an electric motor. In steam driven pumps, the power end is often called the STEAM END. The fluid end is generally called the PUMP END; but it may be called the LIQUID END, the WATER END, the OIL END, or the GAS END, to indicate the nature of the fluid substance being pumped.

Pumps can be divided into groups according to the principles on which they operate. Most pumps fall into five main types: reciprocating, rotary, centrifugal, propeller, and jet. Each type of pump is especially suited for some particular kind of work.

RECIPROCATING PUMPS

The hand water pump commonly used on farms is a good example of the reciprocating pump. The reciprocating pump derives its name from the back and forth or up and down movement of the piston or plunger inside a cylinder. These pumps are used on modern ships as emergency feed water pumps and as fire and bilge pumps. Reciprocating pumps are used for emergency purposes because they are easy to operate and can be started safely by relatively inexperienced

9440

139.34

Figure 10-1.—Operating principle of two types of reciprocating pumps.

personnel. These pumps are also reliable for starting under cold conditions.

A single-acting pump is one which takes a suction on one stroke only, known as the suction stroke. On the return stroke—called the discharge stroke—the liquid is forced out of the cylinder. Figure 10-1 (A) illustrates the operating principle of a single-acting reciprocating pump.

The principal parts of a single-acting reciprocating pump are a cylinder, a piston, and a valve system. The piston fits snugly in the cylinder and is moved up and down in it by the pump shaft. Most of these pumps are steam driven. The pump shaft is a continuation of the piston rod of the steam cylinder.

On the down stroke, the valves in the bottom of the cylinder are closed and the water in the lower part of the cylinder is forced up through the valves in the piston. On the up stroke, the weight of the water above the piston closes the piston valves. As the piston moves upward, it draws the water from the suction line into the cylinder through the cylinder valves. The water above the piston leaves the pump through an outlet line or a spout.

The double-acting pump shown in (B) of figure 10-1 is designed to deliver a steady stream of water under high pressure. Double-acting pumps are also steam driven. The pump is connected directly to the piston rod of the steam cylinder. These pumps have the same general parts and operate on the same general principle as the single-acting type. The valve system is arranged differently and an air chamber is added to maintain the pressure when the piston is at the top and bottom of each stroke.

A stream of water is forced out of the double-acting pump on both the up and the down strokes. On the up stroke, the water above the piston is forced out through the upper outlet valve. At the same time, water is being drawn into the space below the piston through the lower inlet valve. On the down stroke, the water below the piston is forced out of (discharged from) the cylinder through the lower outlet valve and a new charge of water is drawn into the top of the cylinder through the upper inlet valve.

Reciprocating pumps are often called POSITIVE DISPLACEMENT pumps—that is, each discharge stroke displaces a definite amount of liquid, regardless of the resistance against which the pump is operating. A relief valve must be installed in the discharge line to relieve any excess pressure.

The operation of the reciprocating pump generally depends upon a valve system that directs the steam first into one end of the cylinder and then into the other end. The steam is allowed to escape from the cylinder after it has served its purpose. Steam to and from the cylinder passes through two ports (openings), one in each end of the cylinder. This arrangement is quite similar to the manner in which the water passes through the double-acting water pump described previously.

One valve design consists of a D-SHAPED SLIDE VALVE (D-valve) that is actuated by a linkage attached to the piston rod. (See fig. 10-2.) The steam chest which is attached to the cylinder is connected through a stop valve to the auxiliary steam line. When the piston reaches the top of its stroke, the valve-operating mechanism moves the valve down to the position shown in (A) of figure 10-2. The port connecting the steam chest

139.35

Figure 10-2.—Operating principle of D-shaped slide valve of a reciprocating pump.

to the space in the top of the cylinder is uncovered. Steam from the chest flows through this port, exerts a pressure on the top of the piston, and forces it downward.

At the same time, the space below the piston is connected with the exhaust port through a recess in the back of the valve. As the piston moves downward, the steam that fills this space is forced out through the exhaust port.

As the piston nears the bottom of its stroke, the valve mechanism moves the D-valve to the position shown in (B) of figure 10-2. This movement uncovers the lower port. Steam from the chest now flows into the lower part of the cylinder and pushes the piston upward. The upper cylinder port is connected to the exhaust port through the back of the valve. As the piston rises, it pushes the exhaust steam out of the top of the cylinder through the exhaust port.

Figure 10-3 shows the piston valve gear commonly used aboard ship. It performs the same function as the D-valve, but the movement of the valve is controlled by the difference between the inlet and the outlet steam pressure. The piston valve gear consists of a main piston-type slide valve and a pilot slide valve. Since the rod from the pilot valve is connected to the pump rod by a valve-operating assembly, the position of the pilot valve is controlled by the position of the piston in the steam cylinder. The pilot valve furnishes actuating steam to the main piston valve; this in turn admits steam to the top or to the bottom of the steam cylinder at the proper time.

Regardless of the type of valve used, the continued operation of the pump consists of feeding steam into one end of the cylinder and exhausting it from the other end. The direction of steam flow (in and out of the cylinder ports) is reversed at the end of each stroke of the piston.

Starting a reciprocating pump is quite simple. First, open the proper valves in the suction and discharge lines before starting the pump. Next, open the exhaust valve and the cylinder drains. Then, open the throttle valve slightly, or "crack" it to feed enough steam into the cylinder to warm it. (See fig. 10-4.) Adjust the throttle to operate the pump at a slow speed until live steam begins to come out of the drains. Now close the drains and adjust the throttle to operate the pumps at the desired speed.

When securing a reciprocating pump, close the throttle first, and then close the exhaust valve. Next open the cylinder drains and close the valves in the suction and discharge lines.

VARIABLE STROKE PUMPS

Aboard ship, variable stroke pumps (positive displacement) are largely used on electrohydraulic steering gear, elevators, cranes, and anchor windlasses. In these applications, the variable stroke pump is referred to as the A-end of the drive system; and the hydraulic motor which is driven by the A-end is referred to as the B-end. By controlling the pumping action of the A-end, you can run the motor (B-end) in either direction and vary the speed from zero to the maximum rate. Variable stroke pumps are also used on some naval ships as in-port and cruising fuel oil service pumps.

Although variable stroke pumps are often classified as rotary pumps, they are actually reciprocating pumps. They operate on a principle similar to that of a single-acting reciprocating pump. A rotary motion is imparted to a cylinder barrel or cylinder block in the pump by means of a constant-speed electric motor, but the actual pumping is done by a set of pistons reciprocating inside a set of cylinders. The means by which the rotary motion is changed to reciprocating motion is explained and illustrated in the discussion which follows.

Figure 10-5 illustrates the operating principle of a Waterbury variable-volume pump. This pump is used as a variable-speed power transmission in the steering gear and the gun-training mechanism aboard ship. It is also used in those systems where it is necessary to control the pump output within very narrow limits.

In the Waterbury pump the pumping is done by a set of pistons that move back and forth within close-fitting cylinders. The oil enters and leaves the cylinders through ports or passages in the cylinder heads. The pistons are operated by the cam action of an angle plate. This method of changing rotary motion to reciprocating (back and forth) motion is demonstrated by the device shown in figure 10-5.

This demonstrator consists of a cylinder barrel and an angle plate attached to a shaft, as illustrated in (A) of figure 10-5. The angle plate is fastened to the shaft by a universal joint that permits it to tilt in any direction. The connecting rods (piston rods) rest in sockets in the angle plate and are attached to pistons that slide up and down in the cylinders. When the handwheel is turned the complete assembly turns with it.

When you place the demonstrator on a sloping surface the angle plate will tip or tilt and assume the same angle as the block. The pistons on the low slide will be drawn down in the cylinders, and those on the high side will be pushed up. In (A) of figure 10-5, the number 1 piston is in the lowest position; number 3 is in the highest.

Now turn the handwheel to the right, and see what happens. As the far side of the angle plate moves up along the surface of the block, the connecting rods and pistons on the side will be raised. The near side of the plate is moving down along the block surface and the pistons on this side will move down in the cylinders. The operation is continuous. Each piston moves up during half of each revolution around the shaft, and moves down during the other half.

The stroke of the pistons (the distance that they move up and down during each revolution of the shaft) depends on the slope or tilt of the angle plate. In (B) of figure 10-5 the demonstrator is resting on a level surface, and the angle plate is parallel with the bottom of the cylinder barrel. When you turn the handwheel now, the angle plate does not move up and down, and the pistons remain in the same position in the cylinders.

So far, the demonstrator has been used to show that the pistons will move up and down in the cylinders when the shaft is turned with the angle plate tilted. The device can be converted into an oil pump by adding an adjustable tilting box to control the tilt of the angle plate and

38.103

Figure 10-6.—Variable stroke axial piston pump.

placing a valve plate on top of the cylinder barrel. The valve plate has two elongated ports that allow the oil to flow into the cylinders on one side of the pump and out on the other side. When the tilt of the angle plate is increased, the stroke of the pistons is increased and more oil passes through the pump. Tilting the angle plate in the opposite direction reverses the direction of the oil flow.

The Waterbury variable-volume pump has the same principal parts as the demonstrator just described. (Fig. 10-6.) the moving parts are enclosed in a pump case that is kept filled with oil. These pumps are mounted in a

9444

horizontal position and are usually driven by an electric motor.

ROTARY PUMPS

All rotary pumps work by means of rotating parts which trap the liquid at the suction side of the pump casing and force it through the discharge outlet. Gears, screws, lobes, vanes, and cam-and-plunger arrangements are commonly used as the rotating elements in rotary pumps.

Rotary pumps (positive displacement) are most useful for pumping oil and other heavy viscous liquids. They are also used for non-viscous liquids, such as water or gasoline, where the pumping problem involves a high suction lift. Rotary pumps are used for fuel oil service, fuel oil transfer, and lubricating oil service. These pumps are self-priming, because they are able to remove air from the suction lines and produce a high suction lift (or a satisfactory vacuum).

The simple GEAR PUMP, shown in figure 10-7 is frequently used in the lubricating systems of fuel oil and water pumps, forced draft blowers, and other auxiliary machinery. This type of pump has two spur gears which mesh together and rotate in opposite directions; one is the DRIVING *GEAR and the other is the DRIVEN GEAR. The* driving gear is attached to the shaft of the electric motor or steam turbine that drives the pump; the driven gear is in mesh with the driving gear and is driven by it. The gears must fit very closely within the case to keep the liquid from leaking back to the suction side of the pump. The parts are lubricated by the liquid being pumped.

38.108

Figure 10-7.—Action of simple gear pump.

Figure 10-8.—Herringbone gear pump.[38.104]

At first glance you might think that the liquid passes between the two gears. This is not true. *As the gears rotate, the liquid is trapped in the* spaces between the gear teeth and the pump case, and is carried around to the discharge side of the pump. As the teeth come in mesh, the liquid is squeezed out of these spaces and is kept from returning to the suction side of the pump. Pressure is built up and forces the liquid out of the pump into the discharge line.

There are several variations of the simple gear pump. One kind has herringbone teeth (fig. 10-8) which make little noise and maintain an even pressure. Another kind has three lobes on each gear instead of teeth. Lobe pumps and some helical pumps have timing gears that rotate the pump parts. All of these pumps operate on the same principle as the simple gear pump just described.

SCREWS PUMPS represent still another type of positive displacement rotary pumps. In the screw pump, the liquid is trapped and forced through the pump by the action of rotating screws. Screw pumps have few moving parts and no valves to get out of order. They are widely used aboard ships as fuel oil and lubricating oil service pumps. They may have two or three screws, and are divided into high pitch and low pitch types.

The triple screw pump (high-pitch) illustrated in figure 10-9 has three screws or rotors that

47.80

Figure 10-9.—Cutaway view of triple screw, high pitch pump.

revolve within a close-fitting housing. The power rotor in the center is in mesh with (and drives) the two idling rotors (idlers).

The suction line is connected to the pump intake, which in turn opens into the chambers at the ends of the rotors. As the rotors turn, the liquid flows in between the threads at the outer end of each pair of screws. At the end of the first turn, a spiral-shaped slug of the liquid is trapped when the ends of the threads come in mesh again. The threads carry the liquid along within the housing toward the center of the pump, and to the discharge opening.

CENTRIFUGAL PUMPS

Centrifugal pumps are used in the feed, fresh water, and firemain systems of the engineering plant. There are many types of centrifugal pumps (feed water booster, condensate, and fire), but all operate on the same principle. Centrifugal pumps can handle large quantities of a liquid and deliver it at a high pressure. These pumps may be driven by a steam turbine, an electric motor, or a diesel engine. They do not operate on the positive displacement principle, but depend on centrifugal force to move the liquid through the pump and maintain the desired pressure. (See fig. 10-10.)

When a body revolves in a curved path, it exerts a force called "centrifugal force" upon the arm, level, casing, or whatever means is used to restrain it from moving in a straight (tangential) line. For example, centrifugal force is the force that holds the water in a pail when you swing it in a circle over your head. If there happens to be a hole in the bottom of the pail, the water will squirt out, even when the pail is upside down.

The simple centrifugal pump shown in figure 10-10 has only one main moving part. A wheel called an impeller is connected to the drive shaft and rotates within the pump casing. The casing has the same spiral shape as a snail's shell. The water enters the pump through the inlet pipe, which empties into the center of the casing. The location of the outlet passage corresponds to the opening in the snail's shell through which the snail emerges.

The suction connection is so designed that the liquid is guided from the suction chamber of the casing to the center or "eye" of the impeller. As the impeller rotates, it carries the water around with it. The centrifugal force resulting from this rotation pushes the water away from

139.38X

Figure 10-10.—Operating principle of a centrifugal pump.

the center and holds it against the inside of the pump casing. As the water flows along the inside of the spiral-shaped casing, it is diverted through the outlet opening and passes into the discharge line.

Centrifugal pumps are not self-priming; they should never be run while empty. The impeller fits very closely into the sides of the casing and depends on the liquid being pumped to supply the necessary coolant. This type of pump is usually installed below the level of the tank from which suction is to be taken. When the intake valve is opened the liquid flows into the pump and primes it. The vent cock should be opened until all air is purged from the pump casing.

A single-impeller pump will maintain pressures up to 150 psi. Where higher pressures are required the pump is designed with from two to six impellers. The pressure is raised by successive stages. The outlet from the first impeller is connected to the inlet of the second impeller and so on through all the stages.

47.37

Figure 10-11.—Main condenser circulating pump (showing reduction gearing).

PROPELLER PUMPS

Propeller pumps are used on some ships as circulating water pumps (fig. 10-11). Although they are often classified as centrifugal pumps, this classification is incorrect because propeller pumps do not actually use centrifugal force for their operation.

A propeller pump has a propeller closely fitted into a tubelike casing. The propeller pumps the liquid by pushing it in a direction parallel to the shaft.

Propeller pumps must be located either below or only slightly above the surface of the liquid to be pumped, since they cannot operate with a high suction lift.

JET PUMPS

All the pumps previously described require motors or turbines to drive them. However, jet pumps have no moving parts. The flow through the pump is maintained by a jet of water or steam that passes through a nozzle at a high velocity.

Jet pumps are generally classified as EJECTORS (which use a jet of steam to entrain, and transport air, water, or other fluid) and EDUCTORS (which use a flow of water to entrain and pump fluids.) The basic principles of operation of these two devices are identical.

A simple jet pump of the ejector type is shown in figure 10-12. In this pump, steam under pressure enters the chamber (C) through a pipe (A) which is fitted with a venturi-shaped nozzle (B) having a reduced area which increases the velocity of the steam. The fluid in the chamber at point F, in front of the nozzle, is driven out of the pump through the discharge line (E) by the force of the steam jet. The size of the discharge line increases gradually beyond the chamber, in order to decrease the velocity of the discharge. As the steam jet forces some of the fluid from the chamber into the discharge line. pressure in the chamber is lowered and the pressure on the surface of the supply fluid forces the fluid up through the inlet (D) into the chamber and out through the discharge line. Thus, pumping action is established.

Jet pumps of the ejector type are occasionally used on board ship to pump small quantities of drainage overboard. Their primary use on naval ships is to remove air and other noncondensable gases from the main and auxiliary condensers.

Figure 10-13 shows a portable eductor of the type found in damage control lockers. The principle of operation is the same as that described for the ejector type of jet pump; but water is used instead of steam. All the water which enters the large end of the jet must go out through the small end. Since the exit end is smaller than the entrance end, the water leaving the jet will have a greater velocity than it had upon entering the jet. The venturi-shape of the diverging nozzles causes a low pressure area, creating suction which draws water through the strainer and entrains it through the diverging nozzle. This ensures a constant flow.

Eductors may also be used for salvage work and with fog or foam equipment. Eductors will operate when entirely submerged in a flooded compartment and will discharge against a moderate pressure.

Although fire and bilge pumps are still being installed in new ships, fixed-type eductors are the principal means of pumping water overboard through the drainage system. By the use of eductors, centrifugal fire pumps can serve as drainage pumps without having to run the risk of fouling the pump with debris present in the bilges; this is especially useful when there has been battle damage to a ship.

47.48

CONSTANT-PRESSURE PUMP GOVERNORS

Constant-pressure pump governors used in the Navy are applied almost entirely to steam-driven pumps, both rotary and centrifugal types. A constant-pressure pump governor operates to maintain a constant discharge pressure, regardless of pump capacity or output.

The constant-pressure pump governor (sometimes referred to as pressure regulating) consists essentially of an automatic throttling valve installed in the steam supply line to the pump's driving unit. A pipeline connects the governor to the pump's discharge line. Variations in discharge pressure, or in pressure differential, actuate the governor, causing it to regulate the pump speed by varying the flow of steam to the driving unit.

A constant-pressure pump governor for a lubricating oil service pump is shown in figure 10-14. The governors used on fuel oil service pumps and on main feed pumps are of the same type. The size of the upper diaphragm and the

9449

38.90

Figure 10-14.—Constant-pressure pump governor.

amount of spring tension vary on governors used for different services. Detailed information concerning the operation and adjustment of governors can be obtained from chapter 9470 (47) of BuShips Technical Manual.

VALVES

Most of the equipment in the engineering spaces is operated by either opening or closing the valves. A valve is a device for stopping and

controlling the flow of a fluid (liquid or gas) through a pipe or an opening. Valves are installed in every piping system aboard ship. You will find them in the fuel line, the feed water pipes, and the steam lines. In addition to the large valves which control the flow of fluid in the lines, there are small valves which pipe the flow around the larger ones. These valves are called by-pass valves, and are used to equalize the pressures.

Valve designs vary greatly to meet service demands. Most valves may be classified as being either stop valves (globe, gate, plug, piston, and needle valves) or check valves, or combination stop-check valves.

STOP VALVES

Stop valves are used to close off a pipe or opening so that the contained fluid cannot pass through. Some valves can be closed partially to cut down or regulate the flow of fluid.

The typical stop valve consists of the body, an opening (port) through which the fluid flows, a movable disk for closing this port, and some mechanical means for raising and lowering the disk. In the closed position, the disk fits snugly into the port, closing it completely. When the valve is open, the disk uncovers the port, allowing the fluid to pass through. Each type of stop valve has a different mechanical arrangement for closing the port in the valve.

Globe Valves

Globe valves generally derive their name from their body shape. (Other types of valves may also have globular bodies; hence, the name may tend to be misleading.) A cross-sectional view of a globe stop valve is shown in figure 10-15. Globe valves are widely used throughout the engineering plant for a variety of services. These valves may be used partly open as well as fully open or fully closed, and are suitable for use as throttling valves.

38.117

Figure 10-15.—Cross-sectional view of globe stop valve.

The moving parts of a globe valve consist of a disk, valve stem, and a handwheel. The stem, which connects the handwheel and the disk, is threaded and fits into threads in the valve bonnet. When you turn the handwheel the stem moves up or down in the bonnet, carrying the disk with it. The valve is closed by turning the handwheel clockwise.

The valve should never be jammed in the open position. After a valve has been fully opened, the handwheel should be turned toward the closed position one-half turn. Unless this is done, the handwheel is likely to freeze in the open position, and it will be difficult to close the valve. Many valves have been damaged in this manner. Another reason for not leaving globe valves fully open is that it is sometimes difficult to tell if a valve is open or closed. If a valve is jammed in the open position, the stem may be damaged or broken by someone who thinks that the valve is closed, and tries to force it open. Valves that are exceptions to the above rule are called BACK SEATING valves. Sometimes the operation of a back seating valve will require that it be fully opened. Whenever this is so, special instructions to that effect will be given. These valves are designed so that when fully open, the pressure being controlled cannot reach the valve stem packing, therefore eliminating possible leakage past the packing.

The edge of the port where the disk touches it is called the valve seat. The edge of the disk and the seat are machined and ground together to form a tight seal. The rate at which the fluid flows through the valve is regulated by the position of the disk. When the valve is closed, the disk fits firmly against the valve seat. When it is open, the fluid flows through the space between the edge of the disk and the seat.

Packing is placed in the stuffing box or space that surrounds the valve stem, and is held in place by a packing gland. With continued use of the valve, the stem will gradually wear the packing away and a leak may develop. You can generally stop a slow leak by tightening the gland a turn or two. If this fails, pressure should be removed from the valve, and the packing renewed.

Figure 10-16.—Cutaway view of gate stop valve (rising stem type).

Gate Valves

Gate valves operate on the same principle as the globe valve, but have a gate (fig. 10-16) instead of a disk. The port is the full size of the pipe, and extends straight through the valve. The gate is connected to the valve stem and is raised and lowered by turning the handwheel. When the valve is in closed position, the wedge-shaped gate blocks off the port; in open position, the gate is drawn up into a recess in the top of the valve. (See fig. 10-16.)

Gate valves are used where a straight-line flow through the valve is desirable. They do not work well as throttles because they tend to chatter, and are therefore usually operated in the fully open or shut position. They are often used in water lines.

Plug Valves

Plug valves (sometimes referred to as plug cocks) are frequently used in gasoline and oil feed pipes as well as in water drain lines. The ordinary petcock is a good example of this valve.

The body of a plug valve (fig. 10-17) is shaped like a cylinder with holes or ports in the cylinder wall in line with the pipes in which the valve is mounted. Either a cone-shaped or a cylindrical plug, attached to the handle, fits snugly in the valve body. A hole bored through the plug is in line with the ports in the valve body. Turning the plug valve handle (which is in line with the hole in the plug) lines up the hole in the plug with the ports in the valve body, so fluid can pass through the valve. The flow can be stopped by turning the plug 90° (a quarter-turn) from the open position.

Some plug valves are designed as three-way or four-way selector valves. Three or more pipes are connected to a single valve in line with the same number of ports in the cylinder wall. Two or more holes drilled in the plug provide a variety of passages through the valve. When a valve of this kind is located in a fuel line, the liquid may be drawn from any one of two or three tanks be setting the handle in different positions.

Figure 10-17.—Plug valves.

Figure 10-18.—Swing-check valve. 11.319X

Needle Valves

Needle valves are used for making relatively fine adjustments in the flow of fluid. A needle valve has a long tapered point at the end of the valve stem. This needle acts as a disk. Because of the long taper, part of the needle passes through the opening in the valve seat before the needle actually seats. This arrangement permits a very gradual increase or decrease in the size of the opening, and thus allows more precise control of flow than can be obtained with an ordinary globe valve.

Butterfly Valves

Butterfly valves are in limited use for liquid service only. The disk in this type valve is flat, and is operated by turning the hand lever on the stem. When the lever is positioned 90° to the piping, the valve is full open; the valve is in the full closed position when the lever is in line with the piping.

CHECK VALVES

Check valves are designed to permit a fluid to flow through a line in one direction only. They have many uses, both aboard ship and ashore. The air valves in automobile tires, the valves in an ordinary water pump, and the feed water check valves on a steam drum are examples of check valves. All of these valves open and close automatically, but some have a handle or handwheel to lock them closed or limit the size of the opening.

The port in a check valve may be closed by either a disk, a ball, or a plunger. In some valves a spring closes the valve, while in others the weight of the disk or ball holds the valve against the seat. The valve opens when the pressure on the inlet side is greater than the pressure on the outlet side of the valve. It closes automatically when the pressure on the inlet side is less than that on the outlet side. Figure 10-18 illustrates a swing-check valve and figure 10-19 shows a lift-check valve. These valves are often installed in drain lines, where it is important that the flow be in one direction only.

STOP-CHECK VALVES

As we have seen, most valves can be classified as being either stop valves or check valves. Some valves, however, function either as stop valves or as check valves, depending upon the position of the valve stem. These valves are known as STOP-CHECK VALVES.

11.321

Figure 10-20.—Stop-check valves.

Two similar stop-check valves are shown in cross section in figure 10-20. As you can see, this type of valve looks very much like a lift-check valve. However, the valve stem is long enough so that when it is screwed all the way doen it holds the disk firmly against the seat, thus preventing any flow of fluid. In this position, the valve acts as a stop valve. When the stem is raised, the disk can be opened by pressure on the inlet side. In this position, the valve acts as a check valve, allowing the flow of fluid in only one direction. The MAXIMUM lift of the disk is controlled by the position of the valve stem. Therefore, the position of the valve stem can limit the amount of fluid passing through the valve even when the valve is operating as a check valve.

Stop-check valves are used in various locations throughout the engineering plant. Perhaps the most familiar example is the so called boiler feed check valve, which is actually a stop-check valve rather than a true check valve. Stop-check valves are used in many drain lines; on the discharge side of many pumps; and as exhaust steam valves on auxiliary machinery.

THROTTLE VALVES

A throttle valve is installed in the MAIN STEAM LINE just ahead of the engine. It is operated by a handwheel and can be opened or closed quickly for starting and stopping. These valves can also be set in any in-between position to regulate the speed of the engine. Unlike check valves, they are installed so that the steam pressure tends to close rather than open them.

The pressure in the main steam lines of some installations is 600 psi. The disk of a throttle valve 6 inches across has an area of about 28 square inches. Therefore, the force exerted on the valve disk tending to keep it closed is 16,800 pounds (600 x 28). Throttle valves are designed to equalize this force, so that they can be opened easily.

A double-poppet throttle valve is two valves in one. It has two ports and two disks attached to a single stem. Both valves open or close at the same time when the handwheel is turned. The ports and the disks are designed in such a way that the steam tends to close one of the disk

valves and open the other. Figure 10-21 illustrates the operating principle of a double-poppet throttle valve.

The forces exerted on the disks of the double-poppet throttle valve resemble a tug-of-war. The steam pushes down on the top of one disk, and up on the bottom of the other disk. Like the rope in the tug-of-war game, the stem keeps the disks in the same position relative to each other.

139.40

Figure 10-21.—Operating principle of a double-poppet throttle valve.

RELIEF VALVES

Relief valves are installed in the steam, water, air, and oil lines, and on various units of machinery aboard ship. They open automatically when the pressure within the line becomes too high. Relief valves protect piping much the same as fuses protect electrical equipment and wiring in the home. There are many types of relief valves; most relief valves have either a disk or a steel ball acting against a coil spring.

The disktype relief valve in figure 10-22 consists of a valve body, a valve disk, and a stem. The steel spring pushes down on the disk and keeps the valve closed. The force of the spring is generally adjusted by setting an adjusting nut on top of the spring. The inlet side of the valve is connected to the system to be protected.

When the force on the bottom of the disk, exerted by the pressure of the fluid in the line, becomes greater than the compression of the spring, the disk is pushed off the seat, opening the valve. The valve outlet may be opened to the atmosphere in compressed air or steam lines. When the valve is used to protect a pump, its outlet is connected to the suction line leading to the pump; the excess fluid passes through the relief valve, and back to the inlet side of the pump.

The ball-type relief valve shown in figure 10-22 operates on the same principle as the disk valve. The ball valve is generally used on lube oil lines. The operating pressure is regulated by adjusting the threaded plug (not illustrated) which holds the spring in place.

Figure 10-22.—Relief valves.

139.41

REDUCING VALVES

The heating system and the galley operate on low pressure steam. The source of steam for these systems is the boilers, which are under high pressures. Reducing valves are installed in the steam lines to these systems to reduce the pressure. These valves will hold a constant pressure in the delivery lines even if the boiler pressure varies over a wide range.

139.42

Figure 10-23.—The operating principle of a simple reducing valve.

Most reducing valves depend on a balance between the outlet or operating pressure and the pressure of a spring or compressed air in a sealed chamber. Although some of these valves

9455

are quite complicated, the principle on which they operate is easily understood.

The simplified reducing valve in figure 10-23 has a main valve, a piston, and a spring. The compression of the spring pushes the piston to the left and opens the valve. When the steam is turned on, it passes through the open valve and builds up pressure in the outlet chamber. When the force exerted on the piston becomes greater than the force exerted by the spring, the piston moves to the right and closes the valve.

During operation, the outlet steam pressure and spring force remain in ballance with the valve partly open. Any slight variation in outlet pressure will upset this balance. The piston will move and increase or decrease the size of the valve opening and restore the original outlet pressure.

In some valves the spring is replaced by a sealed chamber containing compressed air. The air pressure acts on a diaphragm instead of on a piston. The valve can be set to maintain any desired pressure by adjusting the air pressure in the sealed chamber. Sometimes the diaphragm is located between two chambers, one of them opened to the inlet and the other to the outlet steam. The action of the diaphragm operates a valve which in turn regulates the steam pressure on a piston connected to the main valve. In all reducing valves, the outlet pressure is used to control the rate at which the inlet steam is permitted to pass through the valve.

SAFETY VALVES

Each boiler is fitted with safety valves which allow steam to escape from the boiler when the pressure rises above specified limits. The capacity of the safety valves installed on a boiler must be great enough to reduce the steam drum pressure to a specified safe point when the boiler is being operated at a maximum firing rate with all steam stop valves completely closed. Safety valves are installed on the steam drum and at the superheater outlet.

Several different types of safety valves are used on naval boilers, but all are designed to open completely (POP) when a specified pressure is reached and to remain open until a specified pressure drop (BLOWDOWN) has occurred. Safety valves must close tightly, without chattering, and must remain tightly closed after seating.

It is important to understand the difference between boiler safety valves and ordinary relief valves. The amount of pressure required to lift a relief valve increases as the valve lifts, since the resistance of the spring increases in proportion to the amount of compression. Therefore a relief valve opens slightly at a specified pressure, discharges a small amount of fluid, and closes at a lower pressure which is very close to the pressure that caused it to open.

Can you see why relief valves would not do for boilers? If the valves were set to lift at anything close to boiler pressure, the valves would be constantly opening and closing, pounding the seats and disks and causing early failure of the valves. Furthermore, relief valves would not rapidly discharge the large amount of steam that must be discharged quickly to bring the boiler pressure down to a safe point, since the relief valves would reseat very soon after they opened. (Fig. 10-24 shows a typical safety valve.)

PIPING

Piping is used throughout the engineering spaces. One piping system carries the fuel from the service tanks to the furnace. A second piping system supplies the boiler with feed water. A third piping system carries the steam from the boiler to the engines and other points where it is needed. Still other systems are used aboard ship to carry salt water, fresh water, gasoline, compressed air, and certain gases. The nature of the substances carried in the pipes, as well as the nature of the services performed, makes it necessary to use a variety of materials, sizes, and designs of piping and attached fittings.

PIPING DEFINITIONS

In routine operations aboard ship there is frequent misuse of the terms PIPE, TUBING, and PIPING by strikers and inexperienced naval personnel. As a step toward correcting the misuse of these three terms, the following definitions are offered.

1. A pipe is made of metal such as cast iron, wrought iron, steel, copper, or brass and designated for size by its nominal inside diameter (ID) in accordance with standard IRON PIPE SIZE (IPS), expressed in inches or fractions of an inch from 1/8 inch to 12 inches. Pipe is designated in three grades or weights of wall thickness as STANDARD, EXTRA STRONG, or DOUBLE EXTRA STRONG. The outside diameters (OD) are the same for each of the three wall thicknesses of any pipe with a given IPS dimension, while the actual ID of these three pipes will differ. When the ID measures more than 12 inches, the pipe is designated by its OD.

9456

Figure 10-24.—Steam drum safety valve (nozzle reaction type). 29.219

For example, a 1-inch standard pipe will have an ID slightly over 1 inch, while 1-inch extra stong and 1-inch double extra strong pipes will have lesser ID's due to their greater wall thicknesses. The identical OD's permit standardization in pipe dies and taps.

2. TUBING, unlike pipe, is designated for size by its nominal OD dimension; specified for wall thickness in decimals of an inch; and joined by such methods as flanging, welding, soldering, or brazing. Because it has thinner walls, tubing is much more flexible than the thicker-walled pipe. Refrigeration piping systems are examples of shipboard use of tubing.

3. PIPING is an assembly of pipes or tubing, and fittings, forming a whole or composite part of a system designed for transferring fluids (water, steam, gas, and oil).

PIPING MATERIALS

Most of the piping systems aboard ship are made of steel, copper, brass, or a copper-nickel alloy. Steel is used for the steam and fuel oil lines. Copper tubing may be used for piping that carries fresh water, lube oil, and other materials. Nickel-alloy tubing has exceptional resistance to corrosion, and is used where resistance to

9457

corrosion, is an important consideration, such as in salt water and fresh water lines.

You will often hear the term "alloy" used in connection with the various kinds of metals. A metal is said to be an alloy when it contains other metals in addition to the principal one. A chrome-nickel-steel alloy is made by adding chromium and nickel to the molten steel while it is being manufactured. Stainless steel used aboard ship is a steel alloy that contains chromium and nickel. The alloys of steel, aluminum, and copper are widely used throughout the Navy.

The piping materials MUST be carefully selected from specified standards approved by BuShips—not according to appearance. For example, the 7-inch steel tubing employed for transferring 400 psi, 650°F steam may look the same to you as the 7-inch steel tubing employed for transferring 600 psi, 850°F steam. But the material of the first may be carbon steel; whereas that of the second MUST be molybdenum alloy steel, capable of resisting high temperature and pressure.

11.310X

Figure 10-25.—Standard threaded pipe fittings.

PIPE FITTINGS

A piping system can be made up by joining individual lengths of pipe with unions, couplings, elbows, or other threaded fittings. Piping systems may also be made up by bolted flanges, welding soldering, or by flared couplings.

The water pipes in a home, and some of the low pressure pipes on a ship, are fastened together by THREADED fittings. Standard threaded pipe fittings are shown in figure 10-25.

In high pressure steam lines the lengths of steel pipe are welded together into sections. A flange is welded to the ends of the sections. A suitable gasket is inserted between flanges, and they are drawn tightly together by stud bolts that pass through the holes in the outer edges of the connection. (See fig. 10-26.) Tubing is usually connected by flared couplings (fig. 10-27) or by soldering.

Figure 10-29.—Types of packing.

139960

GASKETS AND PACKING

When leakage occurs in a piping system, it usually occurs at one of the joints. Many methods and materials are used to keep joints from leaking. Flanged joints in piping systems are made up with gaskets in order to make a tight seal and thus prevent leakage. (When the coupling is tightened, the gasket is compressed and seals the joints.) Figure 10-28 illustrates various types of gaskets. Connections in which there are sliding or rotating parts require packing material to seal the joints. Figure 10-29 illustrates several kinds of packing.

It is important that the proper gasket or packing material be used in each application. BuShips Technical Manual, chapter 9950 (95), and other BuShips publications contain information on gaskets and packings. On board ship, tables showing the types of gasket and packing materials approved for various services are posted in the engineering spaces.

Materials used for gaskets include pressed cork, asbestos, soft iron, Monel, metallic cloth,

Figure 10-30.—A. Bilge suction strainer. B. Duplex oil strainer. C. Manifold steam strainer.

039461

and hard fiber sheets. The type of gasket to be used depends upon the pressures and temperatures to which it will be subjected, and in some cases on the nature of the fluid being carried in the piping system.

Packing is used to seal the joints around revolving shafts and valve stems. These units are designed with a space which surrounds the shaft or stem, called a stuffing box. When the packing has been placed in the stuffing box, it is compressed by tightening a gland or nut that screws up against it. Such an arrangement can be seen when taking an ordinary water faucet apart. The packing serves to keep the water from flowing up around the valve stem.

11.325D

Figure 10-31.—A mechanical steam trap.

Packing materials in common use include woven asbestos and rubber; anti-friction metal woven with cotton thread and graphite; spun yarn; and soft metal, flax, and rayon combinations. The type of packing to be used depends upon the service requirements.

STRAINERS

Strainers are installed in almost all piping lines to prevent the passage of foreign matter which might cause damage to machinery. For example, wire mesh basket-strainers are installed on the suction side of many pumps; steam strainers (part C of fig. 10-30) are installed in main and auxiliary steam lines (just ahead of most auxiliary turbines); and duplex strainers (part B of fig. 10-30) are fitted into most lubricating oil and fuel lines so that one strainer may be removed and cleaned without disturbing the flow of oil. A bilge suction strainer is shown in part A of figure 10-30. As you can see, the basket strainer keeps foreign matter from going to the bilge pump suction.

11.326X

Figure 10-32.—Thermostatic steam trap.

Figure 10-33.—Impulse steam trap.

STEAM TRAPS AND DRAINS

Steam traps are installed in steam lines to remove condensate. Some steam traps are suitable for high pressure use, and others for low pressure use. In general, a steam trap consists of a valve and some device or arrangement which will cause the valve to open or close, when necessary, to drain the condensate from the line without allowing the escape of steam. Steam traps are installed at the low point of a system or below a machinery unit that has to be drained. Drains are used to remove condensate while steam lines and steam-driven machinery are being warmed up. A drain usually consists of a section of piping and one or more valves.

There are several types of steam traps in use on naval ships: mechanical (fig. 10-31), thermostatic (fig. 10-32), and impulse (fig. 10-33).

Additional information on steam traps can be obtained from chapter 9480 (48) of the Bureau of Ships Technical Manual.

CHAPTER 11

SHIPBOARD ELECTRICAL EQUIPMENT

On modern naval ships, much auxiliary machinery and equipment is run by electricity. Regardless of rate or rating, every man assigned to a ship will operate some electric device in performing his duties. As a Fireman, you will probably use or operate portable lights, electric drills and grinders, electric heaters, ventilation blowers and fans, electric-driven pumps, and other electrical equipment. Therefore, you should know and observe all applicable safety precautions when working with or around electrical appliances and equipment.

It is beyond the scope of this training course to discuss the theories of basic electricity in detail. This chapter contains information to familiarize you with the different electrical equipment aboard ship, and with what the equipment is designed to do.

Additional information on the basic principles of electricity may be obtained in the Navy training course Basic Electricity, NavPers 10086-A.

INTRODUCTION TO ELECTRICITY

The various techniques and equipment developed from applying the principles of electricity require some degree of theoretical knowledge, as well as practical experience and skill, for safe operation.

Electric cable carries the electric energy produced by the generators to the electric motors where it is expended in performing work.

All materials will conduct electricity but some of them offer more resistance than others. Metals such as silver, copper, aluminum, and iron offer little resistance and are called CONDUCTORS.

In contrast to good conductors, some substances, such as wood, paper, porcelain, rubber, mica, and plastics offer a high resistance to an electric current and are known as INSULATORS. Electric circuits throughout the ship are made up of copper wires covered with rubber or some other insulator. The wire offers little resistance to the current while the insulation keeps the current from passing to the steel structure of the ship.

Definite units have been established to measure electrical properties of conductors and characteristics of electric currents. A brief review of these fundamentals of electricity is given in the sections which follow.

ELECTRIC CURRENT

Current is the rate at which electricity flows through a conductor or circuit. The practical unit, called the AMPERE, specifies the rate at which the electric current is flowing. The term AMPERE (I) is a measure of the intensity or the number of electrons passing a point in a circuit each second. (The flow of current can be compared to the flow of water through a pipe.)

ELECTROMOTIVE FORCE

Before an electric current can flow through a wire there must be a source of electric "pressure" just as there must be a pump to build up water pressure before the water will flow through a pipe. This electric pressure (E) is known as ELECTROMOTIVE FORCE (emf) or VOLTAGE (v); the source may be GENERATOR or a BATTERY.

If you increase the pressure on the electrons in the conductor, a greater current will flow, just as an increased pressure on water in a pipe will increase the flow.

RESISTANCE

Electrical resistance is that quality of an electric circuit that opposes the flow of current through it. The unit of resistance, known as the OHM, is usually expressed as R.

WATT

Power (P) is the rate of doing work. In a direct-current (d-c) circuit, power is equal to

9464

the product of current times voltage, or P = E x I. The practical unit of power is the WATT or KILOWATT (WATTS x 1000).

GENERATOR TYPES AND DRIVES

The generator is the heart of the ship's electrical system. On board any ship, a large amount of electricity is required for the proper provision of air, water, and food. Communications between the various parts of a ship depend largely upon the availability of electric current to operate the ship's announcing system. Radio, radar, and lighting systems, and the training and firing of guns depend upon electricity.

Since a generator runs at greatest efficiency when generating or producing its full rated current output, it is not practicable to have one large generator frequently running at part load. Therefore, two to eight small generators are installed aboard ship, depending upon the specific type ship.

Another reason for installing two or more generators aboard ship is to ensure that, in the event of damage to a generator, there will be enough power and lights available until the defective generator has been repaired. In addition, generators are installed throughout the engineering spaces of a ship so that the electrical plant cannot be destroyed by one or two enemy shells or bomb hits.

Alternating current (a-c) is used aboard the Navy's comtatant ships. The advantages of a-c installations are lower cost, smaller units, and less maintenance. Direct-current (d-c) generators are found on cargo ships, and personnel transports. The d-c motors may be run at variable speeds and are used to run the ship's winches.

D-C GENERATORS AND EXCITERS

A d-c generator is a rotating machine that changes mechanical energy to electrical energy. The essential parts of a d-c generator are the yoke and field windings, which are stationary, and the armature which rotates. In a-c generators, called alternators, the field rotates and the armature is stationary. In order to avoid confusion, the rotating members of d-c generators are called armatures and in a-c generators they are called ROTORS.

There is no difference between d-c generators and exciters. The exciter is a d-c generator which supplies direct current for an a-c generator. In the past, d-c ship's service generators were used aboard ship. At present, practically all ships have 450-volt (60 cycle) a-c ship's service and emergency generators. The d-c generators used in Navy installations for ship's service, or for exciters, are designed to operate at 120

73.161

Figure 11-1—A d-c generator.

139.43X

Figure 11-2.—Low speed engine-driven alternator. A. Stator. B. Rotor.

9465

or 240 volts. The amount of current depends upon the size and design of the d-c generator.

A typical d-c generator is illustrated in figure 11-1. The armature is supported on ball bearings, and the field coil windings create a magnetic field through which the armature windings are rotated. This induces a voltage in the armature windings. The current driven by the induced voltage is circulated through the commutator (on the armature shaft) and carried by the brushes (which ride on the commutator) to the external circuit. Part of the armature current is forced through the field winding to increase and maintain the magnetic strength.

A-C GENERATORS

The general construction of a-c generators is somewhat simpler than that of d-c generators. The heavy current on a d-c generator has to pass through the commutator and brushes. A-c generators do not have a commutator. The heavy current on a-c generators is taken from the stationary part or stator windings. A-c generators have two slip rings which carry a relatively small direct current that is supplied by the exciter to the d-c field winding of the rotor.

A-c generators, like d-c generators, have magnetic fields and an armature. In small a-c generators the armature revolves, the field is stationary, and no commutator is required. In large a-c generators the field revolves and the armature is wound on the stationary member, or stator.

The principal advantages of the revolving-field generators over the revolving-armature generators are as follows:

1. The load current from the stator is connected directly to the external circuit without using slip rings.
2. Only two slip rings are necessary to supply excitation to the revolving field.
3. The stator winding is not subjected to mechanical stresses that are due to centrifugal force.

The a-c generators, or alternators, used in the Navy are divided into two classes: (1) low speed engine-driven alternators, and (2) high speed turbine-driven alternators.

The low speed engine-driven alternator (fig. 11-2) has a large diameter revolving field, with many poles, and a stationary armature. The stator (fig. 11-2A) contains the armature windings. The rotor (fig. 11-2B) consists of salient, or protruding, poles on which are mounted the d-c field windings.

The high speed turbine-driven alternator (fig. 11-3) is connected either directly or through gears to a steam turbine. The enclosed metal structure is part of a forced ventilation system that carries away the heat by circulation of air through the stator (fig. 11-3A) and rotor (fig. 11-3B).

SHIP'S SERVICE TURBINE-DRIVEN GENERATORS

Ship's service generators are so named because they furnish electricity for the service of the ship. Aboard most steam-driven ships of the Navy, these generators are driven by turbines. Large ships may have as many as six or eight ship's service generators.

Destroyers have four turbine-driven ship's service generators (two in the forward engineroom and two in the after engineroom), and two smaller diesel-driven emergency generators.

139.44X

Figure 11-3.—High speed turbine-driven alternator. A. Stator. B. Rotor.

9466

96.17X

Figure 11-4.—A turbine-driven generator set.

The type of ship's service generator commonly used aboard ships of the Navy is illustrated in figure 11-4. Although generator sets (turbogenerators) may be built differently, all have the same arrangement of major parts.

Turbines used for driving the ship's service generators differ from other auxiliary turbines in that they usually operate on superheated steam. These turbines are usually of the axial-flow, multistage, geared type. The turbine exhausts to a separate auxiliary condenser which has its own circulating pumps, condensate pumps, and air ejectors. Cooling water for the condenser is provided by the auxiliary circulating pump, through separate injection and overboard valves.

Provision is made for supplying superheated steam to the ship's service generator turbine from either the main steam line or a special turbogenerator line led directly from the boiler.

77.175

Figure 11-5.—Generator and distribution switchboard—live front.

9467

On some ships, the turbine may—in the event of condenser casualty—be discharged directly to the atmosphere, or to the main condenser when the main plant is in operation.

Because the ship's service generator must supply electricity at a constant voltage and frequency, the turbine must run at a constant speed even though the load will vary greatly. Constant speed is maintained through the use of a speed regulating governor. This turbine also has an overspeed trip, which closes the throttle if the turbine overspeeds and the speed regulating governor fails to function; a back-pressure trip, which closes the throttle if excessive exhaust pressure is built up; and a manual trip which may be used to close the throttle quickly when damage to the turbine or to the generator occurs. The shaft glands of the ship's service generator turbine are supplied with gland-sealing steam; the system is similar to that used for main propulsion turbines. Other auxiliary turbines in naval use are seldom, if ever, provided with gland-sealing systems.

DIESEL-DRIVEN GENERATORS

Practically all Navy ships are equipped with diesel-driven emergency generators. Diesel engines, rather than turbines and reduction gears, are most suitable for this application because of their quick starting ability. Emergency generators furnish power directly to the radio, radar, gunnery, and vital machinery equipment.

The typical shipboard plant consists of two diesel emergency generators, one forward and one aft, in spaces outside the enginerooms and firerooms. Each emergency generator has its individual switchboard and switching arrangement for control of the generator and for distribution of power to certain vital auxiliaries and to a minimum number of lighting fixtures in vital spaces.

The capacity of the emergency unit varies with the size of the ship on which the unit is installed. Regardless of the size of the installation, the principle of operation is the same.

Detailed information concerning the operation of diesel-driven generators can be obtained from appropriate manufacturers' technical manuals.

SWITCHBOARDS

Switchboards consist of panels for mounting the various measuring instruments, indicating devices, and protective and regulating apparatus required for controlling the operation of the generators and the distribution of electric power. A distribution switchboard is provided for each generator or group of generators.

Most Navy ships have from two to four ship's service generator switchboards; small ships, such as destroyers, have two switchboards, whereas large ships may have as many as four switchboards.

Most switchboards have the equipment grouped to form a number of units, each complete with a separate front panel. These panels include the generator unit, bus tie unit, power distribution unit, and lighting distribution unit. (New ships have transformers throughout the ship with lighting distribution panels instead of lighting distribution units.) A number of these units mounted on a common base comprise a section. A switchboard may consist of a single section or of several sections, each complete in itself but connected by cables to form a switchgear group. This arrangement of several small sections lessens the danger of shock, localizes damage from fire, and provides for easy removal of damaged sections for repairs or replacement.

The two types of switchboard construction are live front and dead front. The live front switchboard, shown in figure 11-5, is found only on very old ships where low-voltage and d-c distribution systems are used, and as interior communication switchboards. The dead front switchboard, shown in figure 11-6, is used for all a-c distribution systems and for d-c systems on all new ships. (NOTE: The terminals are accessible on the live front type. In the dead front switchboard, the meters and operating handles are mounted on the panels, and all live parts are located behind the panels.)

GENERATOR AND DISTRIBUTION SWITCHBOARDS

Ship's service 450-volt, a-c switchboards are all of the dead front type. These switchboards are built to provide efficient and safe operation of the electrical system. A typical power distribution system in a destroyer consists of both a forward and after generator and distribution switchboard. All the necessary apparatus for controlling each generator and for distributing its power is incorporated in an associated switchboard.

The forward ship's service generator and distribution switchboard is the control switchboard. It is provided with instruments and controls for the after generator. These instruments

9468

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Figure 11-6.—Generator and distribution switchboard—dead front. 139.45

and controls are necessary to parallel the generators and equalize the load. An automatic voltage regulator is mounted on each switchboard to control the generator field excitation and to maintain a constant a-c generator voltage throughout the normal changes in load.

Two diesel emergency generator sets are provided to supply electric power for limited lighting and for vital auxiliaries in the event of failure of the ship's service power. One unit is located in the forward emergency generator room and the other unit is located in the after emergency generator room. The forward emergency switchboard is normally energized from the forward ship's service switchboard and the after emergency switchboard is energized from the after ship's service switchboard.

D-c power distribution systems are in use on some older ships that have large deck machinery loads. These systems, which consist of the ship's service generator and distribution switchboards, are similar to the a-c systems. On new ships, d-c power is provided at the load with rectifiers.

9469

137

COMPONENTS OF A SWITCHBOARD

Each switchboard includes one or more units, a bus tie unit, a power distribution unit, and lighting distribution units or transformers and lighting distribution panels. Large circuit breakers are used to connect ship's service and emergency generators to the power distribution system. They are also used on bus ties and shore connection circuits. In accordance with the electric load, smaller circuit breakers are also installed on switchboards and on distribution panels throughout the ship.

Circuit Breakers

Circuit breakers (see fig. 11-7), equipped with individual automatic tripping devices, are used to isolate faulty circuits, and to serve as overload protection. These circuit breakers are a part of the switchboard equipment. Circuit breakers are used in circuits that require large amounts of current, rather than fuses. They can be operated for an indefinite period, and their action can be controlled with greater accuracy.

Overload circuit breakers open automatically when the current (load) on the circuit exceeds a preset value for which the circuit breaker is set. Circuit breakers used with shipboard equipment are not susceptible to tripping under successive heavy shocks, such as those caused by gunfire. Circuit breakers are used on all rotating electrical machinery and feeders to vital loads. such as turrets and searchlights.

In addition to overload coils, reverse current trip coils are provided on d-c circuit breakers. These units are designed to open if the direction of current flow changes.

Figure 11-7.—Circuit breaker.

27.74

178470

Switches

A switch is a device for making or breaking an electric circuit. The KNIFE SWITCH, with the associated fuses, is used on small live front switchboards that distribute low voltage.

The ROTARY SNAP SWITCH, used mostly for lighting circuits, is a device that opens or closes a circuit widh a quick motion. A rotary snap switch, shown in figure 11-8, consists of

Figure 11-8.—Rotary snap switch. 12.69

one or more sections, each of which has a rotor and a stationary member. A shaft with a handle at one end extends through the center of the rotors. The rotors are snapped in and out of the stationary contacts on the "pancake" sections. When the handle is turned slightly, it winds a coil spring on the shaft. As the handle is turned farther the coil spring snaps the rotor contacts in or out of the stationary contacts. Snap switches are used extensively in the distribution sections of IC switchboards and in lighting circuits.

Indicator Lights

To provide information to the operator, small colored lights are usually installed on switchboards. The two most common colors used on older ships for indicator lights are blue and amber. Blue indicator lights show the operator which generator and bus tie circuit breakers are closed. When these circuit breakers are opened, the blue light will go off and the amber light will burn. On new ships, yellow is used instead of amber.

Light bulbs are also used on the switchboard for other pusposes. A set of lights is used when paralleling generators. These lights are called SYNCHRONIZING LAMPS. A meter (synchroscope) is generally used for paralleling generators. However, lights are installed on the board as a safety precaution.

White lights are used for checking grounds or low insulation of electrical circuits. These lights are known as GROUND-DETECTOR LIGHTS.

Voltage Regulators

Voltage regulators, installed on the associated switchboards, are used for a-c ship's service and emergency generators. The voltage regulator is used to maintain the generator voltage within specified limits. The switchboard operator can adjust (set) the voltage of the generator at any value within normal limits. When additional loads are applied on the generator, there will be a tendency for the voltage to drop. The automatic regulator keeps the voltage of the generator constant at different loads.

Rheostats

Rheostats are generally used on d-c panels to regulate the amount of current through the field windings of a generator. The rheostat contains resistors which are connected in series. The center part of the rheostat can be rotated so that movable electrical contacts select different amounts of resistance. By adjusting the amount of resistance in the circuit, it is possible to increase or decrease the current and control the voltage.

Indicating Meters

All the important switchboards aboard ship are provided with electrical meters of various types. Electrical meters, somewhat like gages and thermometers, show the operator what is taking place in the electrical machinery and systems. Electrical meters are of two general types: installed meters (on switchboards) and portable meters. Some of the common meters that are used on switchboards are voltmeters, ammeters, kilowatt meters, and frequency meters.

059471

ELECTRIC MOTORS

Electric motors are used aboard ship to operate guns, winches, elevators, compressors, pumps, ventilation systems, and other auxiliary machinery and equipment. There are many reasons for using electric motors; they are safe, convenient, easily controlled, and easily supplied with power.

A motor changes electrical energy, produced by the generators, into mechanical energy. There are important reasons for changing mechanical energy to electrical energy and then back to mechanical energy. One reason is that electric cables can be led through decks and bulkheads with less danger to watertight integrity than steam pipes or mechanical shafts. Another reason is that damage to a steam line could cause steam to escape, resulting in personnel injury. If an electric cable is used and a fault occurs, the circuit breaker protecting the cable opens automatically.

D-C AND A-C MOTORS

The a-c motor, smaller and requiring less maintenance than the d-c motor, is extensively used by the Navy. The d-c motor, which is built like a d-c generator, is used mostly on submarines, some auxiliary ships, and some small ships.

Most of the a-c motors used on board ship are three-phase 60 cycle, 440-volt motors. The induction motor is commonly used by the Navy. Although most a-c motors have one speed, a number of motors with two speeds, such as those on ventilation systems, are installed aboard ship.

MOTOR CONTROLLERS

Controlling devices are used to start, stop, speed up, or slow down motors. In general, these controllers are standard equipment aboard ship and are either manual, semiautomatic, or automatic. They are dripproof and shock resistant. In some installations the controllers are operated by remote control, with the switch located at a convenient place.

These motor control devices (controllers, master switches, and electric brakes) function to protect the equipment to which they are connected. Controllers are designed to provide protective and governing features for every type of shipboard auxiliary. To govern the controllers themselves, master switches of various types are installed. Electric brakes are used to bring a load to rest, or to hold it at rest, when electric power to the motor is cut off. Aboard ship, electric brakes are used primarily on hoisting and lowering equipment such as cranes, winches, and windlasses.

Most controllers function simply to start or to stop auxiliary machinery, but some controllers also provide for reversal of direction or two-speed control. Motor controllers, sometimes called starters, have overload protective devices to prevent the motor from burning out. Most controllers cut out automatically when the electric power fails, and have to be restarted at the controller.

BATTERIES

Aboard ship, batteries are one of the sources of electricity for emergency and portable power. Dry cell batteries are used primarily for flashlights, hand lanterns, and test equipment. Storage batteries are also used for emergency equipment on board ship and for ship's boats. (Boats, like automobiles, use batteries for starting and lighting.) The storage battery is used, as a source of electrical energy, for emergency diesel generators, gyrocompasses, and emergency radio.

Since you may act as a boat engineer, you should be familiar with safety precautions to be observed when working around batteries. Batteries must be protected from salt water, which can mix with the electrolyte (acid solution) and give off poisonous fumes. Salt water in the electrolyte also sets up a chemical reaction which will ruin the battery.

Storage batteries, when being charged, give off a certain amount of hydrogen gas. Battery compartments should be well ventilated. Flames or sparks of any kind, including lighted cigarettes, should never ba allowed in the vicinity of any storage battery that is being charged. When the battery is low or does not perform properly, the boat engineer should notify the Electrician's Mate (EM) so that the faulty condition can be corrected promptly.

PORTABLE EQUIPMENT

Aboard any ship there will be small electric powered equipment, such as portable electric drills, hand lanterns, small ventilation blowers, and handtools.

9472

HAND LANTERNS

Relay-operated hand lanterns, usually called battle lanterns, are powered by dry cell batteries. Hand lanterns are provided to give light when the lighting systems fail. These lanterns are placed in spaces where continual illumination is necessary, such as machinery spaces, control rooms, essential watch stations, battle dressing stations, and escape passages. The battle lantern should not be removed from its mounting bracket except in an emergency. Don't use it as a flashlight.

The relay control boxes for battle lanterns are connected to the emergency lighting supply circuit (or to the ship's service lighting circuit) in which the lantern is installed. If power in the circuit fails, the relay opens and the batteries light the lantern.

Hand (battle) lanterns are capable of operating for approximately 10 continuous hours (or the equivalent) before the light output ceases to be useful.

Similar hand lanterns, which are NOT connected to relays, are installed throughout the ship to provide illumination in stations which are manned occasionally. These lanterns are manually operated. When used in an emergency, these manually operated hand lanterns should always be RETURNED TO THEIR ORIGINAL LOCATION.

SEALED BEAM LIGHTS

Sealed beam lights, a type of flood lantern, are used to give high-intensity illumination in damage control or other emergency repair work. These units consist of a sealed beam light similar to that used for automobiles. The sealed beam light, powered by four small wet cell storage batteries, is mounted on the battery case, and fitted with a handle for convenience in carrying. A sealed beam lamp will operate for the equivalent of 3 continuous hours before the battery requires recharging. When the battery is at full charge, the beam has an intensity which is similar to that of the headlight of an automobile. At the end of 3 hours the light output will gradually drop to about one-half of its original brilliance.

PORTABLE EXTENSION LIGHTS

Portable extension lights are widely used aboard ship, especially in the engineering spaces. Adequate lighting is necessary when maintenance work is being done or when machinery repairs are being made.

The portable extension light and cord should be in good condition. The cord should be free from cuts or damaged areas. The light and cord should be free from moisture, oil, and grease.

Care should be taken to see that the extension light has the required metal wire guard. This metal wire guard is installed as a safety precaution; never remove the guard from the extension light. Unguarded electric light bulbs are dangerous as well as easily broken. Men have received fatal shocks from broken light bulbs.

Care should be taken not to lay extension cords across decks or other places where they may be damaged. If possible, cords should be run overhead and tied in place. Also, keep rubber cords away from hot steam piping as well as away from oil and paint. Avoid running an extension cord through a watertight hatch or door.

An extension light should be returned promptly to its proper stowage place after the work for which it was used has been finished. The light should be clean, dry, and in good condition. Defective extension lights (including lights without guards) should be brought to the electric shop for repairs immediately.

PORTABLE TOOLS

Proper care and precautionary measures should be taken in handling and working with portable tools such as electric drills and grinders. Protective goggles must always be worn while using tools such as wire brushes and grinders.

There is an inherent danger in the use of portable electric tools because of the possibility of electric shock. The Electrician's Mates are required to make routine tests of electrical tools to ensure that they are safe to use. Portable tools in use on Navy ships are provided with a grounded plug and a ground wire connected to the metal part of the tool. Grounded receptacles are installed throughout the ship. The cords for portable electric tools contain three conductors; the third conductor is used to ground the portable tool to the ship. These precautions are taken to prevent operators of portable tools from receiving a dangerous electric shock.

SHIPBOARD ELECTRICAL SYSTEMS AND CONNECTIONS

As a Fireman, you should be familiar with the power distribution systems, the lighting

9473
STAC

distribution systems, and shore power connections. These are described briefly in this course. Greater detail on this and other shipboard electrical equipment is available in chapter 9620(62), Bureau of Ships Technical Manual.

POWER DISTRIBUTION SYSTEMS

The power distribution system connects the generators, which furnish electric power, to the power-driven equipment installed throughout the ship. From the generator switchboards, a distribution system consisting of feeders, mains, submains, load center panels, distribution panels, and distribution boxes conveys power to every part of the ship. The most important auxiliaries are supplied with normal, alternate, and emergency feeders, each with a separate source of power. Casualty power systems are installed aboard ships in order to provide electrical connections when both ship's service and emergency electrical systems are damaged.

For loads near a switchboard, and for such large and important loads as steering gears, anchor windlasses, and turrets, power is supplied directly from the ship's service generator and the distribution switchboard. In large installations, power distribution to other loads is from the generator and distribution switchboards to load centers, then to distribution panels, and finally to the loads. Load centers are not provided in small installations.

LIGHTING DISTRIBUTION SYSTEMS

Lighting distribution systems are necessary not only for lighting the ship but also for assisting personnel controlling damage. Aboard combatant ships two lighting systems are installed: ship's service lighting and emergency lighting. The former normally supplies all lighting fixtures. Emergency lighting circuits are supplied to vital machinery spaces, the radio room, the combat information center, and other vital spaces. The emergency lighting system receives power from the ship's service generators, but if normal power is lost, the emergency system is automatically cut in on the emergency generators. Lighting distribution systems are similar to power distribution systems, except that they (1) are more numerous, (2) have lower voltages (117 v), and (3) have smaller panels and cables.

Lighting distribution requires a variety of panels and distribution boxes, for connecting loads with power supply. High-voltage feeders from switchboards are stepped down from 450 v to about 117 v by transformers when they are connected to distribution panels. Circuits emerging from distribution panels are connected to feeder distribution boxes. The feeder distribution box, which is similar to the distribution panel, only has a few branch circuits. The distribution boxes convey power directly to the actual load circuits.

SHORE POWER CONNECTIONS

Shore power connections are installed at or near suitable weather deck locations to which portable cables from the shore, or from a ship alongside, can be connected. Power can be supplied through these connections to the switchboard when ship's service generators are not in operation.

ELECTRICAL SAFETY PRECAUTIONS

There are certain safety precautions which should be observed when working with or around electrical appliances and equipment.

Some of the most common electrical safety precautions to be observed by personnel are as follows:

1. Do not attempt to maintain or repair electric equipment. Leave the electrical work to the Electrician's Mates and I.C. Electricians.
2. Observe and follow all pertinent instructions and electric warning signs on board ship.
3. Observe all safety precautions regarding portable electric lights and tools.
4. Remember that especially on board ship 117-volt electricity is very dangerous.
5. Do not touch or operate an electrical switch that has a warning tag attached to it.
6. Do not go behind electrical switchboards.
7. Do not touch live electric wires and fittings.
8. Never remove the wire metal guard from a portable extension light.
9. Do not remove steamtight globes from lighting fixtures.
10. Do not remove battle lanterns from their locations.
11. Do not use manually operated hand battle lanterns for unauthorized purposes. Each person should have his own flashlight.
12. Do not use electric cables for hoisting or supporting heavy weights, or the wireways for storage.
13. Prevent water from getting into electrical equipment.
14. Remember that a flame, spark, or lighted cigarette can cause a disastrous battery explosion.

9474

15. Remember that electrolyte from a storage battery can cause severe burns, and can damage equipment or clothing.

16. When repairing equipment that is driven by a motor, have an electrician disconnect the circuit and tag it as out of commission.

17. Do not start or operate electric equipment when flammable vapors are present.

18. Take time to learn the electrical safety precautions that are applicable to your assigned duties and duty station, whether it be the fireroom, engineroom, electric shop, or other duty or station assignment. (A thorough understanding of electrical safety precautions will help prevent injury to yourself and damage to equipment which you may be called upon to operate.)

19. If you are ever in doubt about the operating condition of electrical equipment, call an electrician.

8475

CHAPTER 12

INTERNAL COMBUSTION ENGINES

Most of the machinery and equipment of large Navy ships utilizes steam as the working fluid in the process of changing thermal (heat) energy to mechanical energy. This chapter deals primarily with internal combustion engines, in which a mixture of air and fuel serves as the working fluid.

Internal combustion engines are used extensively in the Navy, serving as propulsion units in a variety of installations such as ships, boats, airplanes, and automotive vehicles (trucks and buses). Internal combustion engines are also used as prime movers, or energizing units, for auxiliary machinery. In most shipboard installations, internal combustion engines are of the RECIPROCATING type. In relatively recent years, however, GAS TURBINE engines have been placed in Navy service as power units. Since the majority of the engines in service in the Navy are of the reciprocating type, the discussion which follows will deal primarily with reciprocating engines.

RECIPROCATING ENGINES

The internal combustion engines (diesel and gasoline engines) with which you will be working are machines that convert heat energy into mechanical energy. Diesel and gasoline engines are of the reciprocating type.

The general trend in Navy service is to install diesel engines rather than gasoline engines, unless special conditions favor the use of gasoline engines. Small boats are used in conjunction with airplane facilities are frequently powered with gasoline engines because the available fuel supply is gasoline. In addition, gasoline engines are used in many installations because of their small size or a lack of suitable diesel engines.

IGNITION PRINCIPLES

The gasoline and diesel engines differ principally in that the former has a carburetor and a spark ignition system. The fuel and air for the SPARK IGNITION (GASOLINE) ENGINE is mixed in the carburetor. This mixture is drawn into the cylinders where it is compressed and ignited by an electric spark.

The COMPRESSION IGNITION type engine is commonly known as a DIESEL ENGINE. The diesel engine takes in atmospheric air, compresses it, and then injects the fuel into the cylinders. The heat generated by compression ignites the fuel, hence the term "compression ignition" is used for diesel engines.

OPERATING CYCLE

All reciprocating engines have a definite cycle of operation. It is necessary to atomize the fuel, get into the cylinders, ignite and burn it, and dispose of the gases of combustion. All reciprocating internal combustion engines operate on either a 2-stroke or a 4-stroke cycle. A stroke is a single up or down movement of the piston, or the distance a piston moves between limits of travel. Each piston executes two strokes for each revolution of the crankshaft. The number of piston strokes occurring during any one series of operations (cycle) is limited to either two or four, depending upon the design of the engine.

In FOUR-STROKE-CYCLE engines, each piston goes through four strokes and the crankshaft makes two revolutions to complete one cycle. Each piston is delivering power during one stroke in four, or each piston makes one power stroke for each two revolutions of the crankshaft.

Let us use one cylinder of a diesel engine to trace its operation through the four strokes that make up a cycle. (See fig. 12-1.) The engine parts shown in this figure include only a cylinder, a crankshaft, a piston and connecting rod, and the inlet and exhaust valves. To simplify the diagrams (A thru D), the valve-operating mechanism and the fuel system have been omitted.

In part A of figure 12-1 the intake valve is open and the exhaust valve is closed. The piston

9476

is moving downward and drawing a charge of air into the cylinder through the open valve. This portion of the cycle during which the piston is moving downward is called the INTAKE STROKE.

When the crankshaft has rotated to the position shown in B of figure 12-1, the piston has moved upward, on the COMPRESSION STROKE, almost to the top of the cylinder. Both the intake and exhaust valves are closed during this stroke. The air which entered the cylinder during the intake stroke is compressed into the small space above the piston. The volume of this air may be reduced to less than 1/16 of what it was at the beginning of the stroke.

The high pressure which is a result of this great reduction in volume raises the temperature of the air far above the ignition point of the oil. When the piston nears the top of the compression stroke, the charge of fuel is forced into the cylinder through the injection valve. The air which has been heated by compression ignites the fuel.

During the POWER STROKE, indicated in C of figure 12-1, the inlet and exhaust valves are both closed. The increase in temperature resulting from the burning fuel greatly increases the pressure on top of the piston. This increased pressure forces the piston downward and rotates the crankshaft. This is the only stroke in which power is furnished to the crankshaft by the piston.

During the EXHAUST STROKE, shown in D of figure 12-1, the exhaust valve is open and the intake valve remains closed. The piston moves upward, forcing the burned gases out of the combustion chamber through the exhaust valve. This stroke, which completes the cycle, is followed immediately by the intake stroke of the next cycle, and the sequence of events continues to be repeated.

The 4-stroke-cycle gasoline engine operates on the same mechanical, or operational, cycle as the diesel engine. In the gasoline engine, the fuel and air are mixed in the carburetor and the mixture is drawn into the cylinders through the intake valve. The fuel-air mixture is ignited near the top of the compression stroke by an electric spark which passes between the terminals of the spark plug.

The principal difference in the cycles of operation for diesel and gasoline engines involves the admission of fuel and air to the cylinder. While this occurs as one event in the operating cycle of a gasoline engine, it involves two events in diesel engines. There are six main events taking place in the diesel cycle of operation (intake of air, compression of air, injection of fuel, ignition and combustion of charge, expansion of gases, and removal of burned gases), and five in the cycle of a gasoline engine (fuel is not injected in such an engine).

Figure 12-1.—The 4-stroke diesel cycle.

TWO-STROKE-CYCLE diesel engines are widely used by the Navy. The Navy uses some gasoline engines that operate on the 2-stroke cycle; they are used principally to drive portable pumps.

Every second stroke of a 2-stroke-cycle engine is a power stroke. The strokes between are compression strokes. The intake and exhaust functions take place rapidly near the bottom of each power stroke. With this arrangement there is one power stroke for each revolution of the crankshaft, or twice as many as in a 4-stroke-cycle engine.

The steps in the operation of a 2-stroke-cycle engine are shown in figure 12-2. The cylinder shown has an exhaust valve but no intake valve. (Other designs have both intake and exhaust ports and include no valves.) The air enters the combustion chamber through ports (openings) in the cylinder wall; these ports are uncovered by the piston as it nears the bottom of each stroke.

In A of figure 12-2, the piston is moving upward on the compression stroke. The exhaust valve and the intake ports are closed, and the

Figure 12-2.—The 2-stroke diesel cycle.[54.20]

piston is compressing the air trapped in the combustion chamber. At the top of the stroke, with the piston in the position shown in B of figure 12-2, fuel is injected (sprayed) into the cylinder and then ignited by the hot compressed air.

In C of figure 12-2, the piston is moving downward on the power stroke. The exhaust valve is still closed and the increased pressure, resulting from the burning fuel, forces the piston downward and rotates the crankshaft.

As the piston nears the bottom of the power stroke, shown in D of figure 12-2, the exhaust valve opens and the piston continues downward to uncover the intake ports. Air delivered under pressure by a blower or from the crankcase is forced into the cylinder through the intake ports, and the burned gases are carried out through the exhaust valve. This scavenging operation takes place almost instantly and corresponds to the intake and exhaust strokes of the 4-stroke cycle.

You might expect a 2-stroke-cycle engine to develop twice as much power as a 4-stroke-cycle engine; however, it does not because a certain percentage of the engine's power is required to drive the blower. Nevertheless, 2-stroke-cycle diesel engines give excellent service. Small gasoline engines operating on the 2-stroke-cycle principle operate satisfactorily, but the larger sizes are less popular.

DIESEL ENGINES

The diesel engines used in small boats look very much like the gasoline engine in an automobile. Each cylinder in the diesel engine is equipped with an ejector and an injector pump; this equipment injects fuel into the cylinder at the proper time. On the gasoline engine, the carburetor provides the proper mixture of gasoline and oil for the cylinder. Most boat engines have a sea water heat exchanger instead of the conventional radiator. Although different makes and models of diesels vary widely, they all have the same essential parts.

POWER SYSTEM

The main working parts of the engine transmit power from the cylinders to the driveshaft. These parts include the cylinders, pistons, connecting rod, and the crankshaft. The cylinders of most marine engines are contained in a single block or crankcase of iron. Each cylinder is lined with a special hardened steel sleeve called a cylinder liner. The upper end of the cylinder is covered by a cylinder head.

The pistons are connected to the crankshaft by connecting rods, which transmit power from the pistons to the crankshaft and convert their reciprocating motion to the rotary motion of the crankshaft. The rods are joined to the pistons by piston pins (wrist pins) and are connected to the crankshaft by connecting rod bearings. (See fig. 12-3.) A seal is provided between each piston and the cylinder wall. This is accomplished by rings on the pistons. As the piston moves up and down, the rings press against the cylinder wall, thus preventing the air or gases from passing down into the crankcase or the oil in the crankcase from working up past the rings.

The rotating force of the crankshaft is used to drive such items as reduction gears, propeller shafts, generators, and pumps. During three of the strokes of a 4-stroke-cycle engine, the rotary motion of the crankshaft is moving the piston up and down.

VALVE MECHANISM

The valves are opened by the action of a camshaft, driven by the crankshaft through a train

CT48
.9478

Figure 12-3.—Piston and connecting rod parts. 75.59X

of gears. The camshaft extends the length of the engine and carries one or more cams for each cylinder. The shaft is cylindrical with irregular shaped cams. Each cam is partly circular in outline but carries a LOBE (NOSE) which gives it an egg-shaped appearance as shown in figure 12-4. The circular part of the cam is called the CAM FLAT or base circle.

The camshaft functions to give an intermittent reciprocating motion, as it rotates. A cam follower or roller, riding on the rotating cam, is lifted each time the lobe or cam nose comes around.

The valve mechanism of a 2-stroke-cycle diesel engine is shown in the cutaway views that appear in figure 12-4. This engine has two exhaust valves that are opened at the same time by the action of a single cam. They make a tight fit in the exhaust openings (ports) in the cylinder head and are held in the closed position by the compression of the valve springs. The rocker arm and bridge transmit the reciprocating motions of the cam roller to the valves.

In A of figure 12-4, the cam roller is riding on the base circle of the cam and the valves are closed. As the camshaft rotates, the cam lobe or nose rides under the roller and raises it to the position shown in B of figure 12-4. When the roller is lifted, the arm rotates about the rocker shaft and the opposite end of the arm is lowered. This action pushes the bridge and valves down against the pressure of the valve springs and opens the valve passages.

On some types of engines, the camshaft is located near the crankshaft. In these designs the action of the cam roller is transmitted to the rocker arm by a push rod. In some engines, the valves are inverted and are located in recesses at the side of the cylinders. With this arrangement, the valve stems may ride directly on the cams or they may be separated by a short steel shaft and roller called a TAPPET assembly.

The camshaft must be timed with the crankshaft so that the lobes will open the valves in each cylinder at the correct instant in the operating cycle. In the 2-stroke cycle the exhaust valves are opened for only a short time near the bottom of the power stroke to permit the burned gases to escape. Since the cycle is completed in one revolution, the camshaft rotates at the same speed as the crankshaft.

The 4-stroke-cycle engine has an intake and an exhaust valve in every cylinder. Each valve is operated by a separate cam. The intake valve is held open during the intake stroke, and the exhaust valve is opened during the exhaust stroke. Since two revolutions of the crankshaft are necessary to complete a 4-stroke cycle, the camshaft of these engines turns only half as fast as the crankshaft.

9479

139.46

Figure 12-4.—Cutaway of a cylinder head, showing the valve-operating mechanism.

75.151

Figure 12-5.—A 2-stroke-cycle engine cylinder with the piston at the bottom of the power stroke.

AIR SYSTEM

In the 4-stroke-cycle engine, the air enters the cylinders through the intake valve. As each piston moves downward on the intake stroke, the volume of the combustion chamber increases and the pressure decreases. The normal atmospheric pressure then forces the air into the cylinder through the intake valve.

Since the 2-stroke-cycle engine does not go through an intake stroke, a means must be provided to force air into the cylinders. The air enters through intake ports, uncovered when the piston approaches the bottom of the power stroke. (See fig. 12-5.) Since the exhaust valves are open when the intake ports are being uncovered, the incoming air forces the burned gases out through the exhaust valves and fills the cylinder with a supply of fresh air.

On the compression stroke, the exhaust valves are closed, the intake ports are covered, and the air is trapped in the cylinder. The rising piston compresses the air and raises its temperature. By the time the piston reaches the top of the stroke, the volume of the combustion chamber has been greatly reduced. The relation between the volume of the cylinder with the piston at the bottom of its stroke and the cylinder volume with the piston at the top of its stroke is called the COMPRESSION RATIO. Compressing the air to 1/16 of its original volume would represent a compression ratio of 16 to 1.

As the compression ratio is increased, the temperature of the air in the cylinder increases. Gasoline engines operate at compression ratios between 4 to 1 and 8 to 1, but compression ratios of diesel engines range between 12 to 1 and 16 to 1. This means that on the compression stroke of a diesel engine the air is compressed to a range of 400 to 600 psi; this results in a temperature ranging from 700° to 800°F. However, when the fuel is injected into the cylinder and begins to burn, the pressure may increase to more than 1500 psi and the temperature may rise as high as 1800°F.

9480

2.67 X

Figure 12-6.—The fuel supply system of a General Motors portable diesel engine.

FUEL SYSTEM

The fuel system of the diesel engine draws fuel oil from the service tank and injects it into the engine cylinders. Figure 12-6 shows the units found in a typical fuel system of the unit injector type. The fuel pump draws the fuel oil from the tank through a primary filter and delivers it under low pressure to the injector by way of the secondary filter. The injector, operated by a rocker arm, meters, pressurizes, and atomizes the fuel as it is injected into the combustion chamber. The outlet line carries the excess fuel oil from the injector back to the fuel tank. In some installations, a transfer pump is installed between the tank and the primary filter. In other installations, the injection pump and injection nozzles are separate units instead of a combined unit as shown in figure 12-6.

A diesel engine will not operate efficiently unless clean fuel is delivered to the injector or injection nozzles. As the fuel oil is pumped into the fuel tanks, it should be strained through a fine mesh screen. The larger particles of the solids suspended in the fuel are trapped in the primary screen. The secondary filter separates the finer particles of foreign matter that pass through the primary filter screens. The final filtering takes place within the injector. Most filters have a drain plug for removing the water, sludge, and other foreign matter. The filter should be drained once a day.

There are many methods of fuel injection and just as many types of injection pumps and nozzles. The unit injector shown in figure 12-6 consists basically of a small cylinder and a plunger, and extends through the cylinder head to the combustion chamber. A cam, located on the camshaft adjacent to the cam that operates the exhaust valves, acts through a rocker arm and depresses the plunger at the correct instant in the operating cycle.

When the injector plunger is depressed, it discharges a fine spray of fuel into the cylinder, through small holes in the nozzle. The amount of fuel injected on each stroke of small boat engine fuel pumps is very small. The smooth operation of the engine depends to a large extent on the accuracy with which the plungers inject the same amount of fuel into every cylinder.

The amount of fuel injected into the cylinders on each stroke is controlled by rotating the plungers of a unit injector. The throttle, which regulates the speed of the engine, is connected to the injectors through a suitable linkage. Changing the throttle setting rotates the plungers and varies the amount of fuel injected into the cylinders on each stroke.

LUBRICATION SYSTEM

The lubrication system of an internal combustion engine is very important. If the lubricating system should fail, not only will the engine stop but many of the parts are likely to be damaged beyond repair. Therefore when lubrication failure occurs, the engine can seldom be run again without a major overhaul.

The lubricating system delivers oil to the moving parts of the engine to reduce friction and assist in keeping them cool. Most diesel and gasoline engines are equipped with a pressure lubricating system that delivers the oil under pressure to the bearings and bushings, and also lubricates the gears and cylinder walls. The oil usually reaches the bearings through passages drilled in the framework of the engine. The lubricating

081481

29.96

Figure 12-7.—Basic units and oil passages of a pressure feed lubrication system.

system of a typical diesel engine is shown in figure 12-7.

Many methods of lubricating the individual parts of each type of engine are in use in the different engine models. Generally speaking, the oil is fed from the main gallery through individual passages to the main crankshaft bearings and one end of the hollow camshaft. All the other moving parts and bearings are lubricated by oil drawn from these two sources. The cylinder walls and the teeth of many of the gears are lubricated by oil spray thrown off by the rotating crankshaft. After the oil has served its purpose, it drains back to the sump to be used again.

9482

The oil pressure in the line leading from the pump to the engine is indicated on a Bourdon-type pressure gage. A temperature gage in the return line provides an indirect method for indicating variations in the temperature of the engine parts. Any abnormal drop in pressure or rise in temperature should be investigated at once. It is advisable to secure the engine until the trouble has been located and corrected.

All of the engine parts are lubricated with oil delivered by the gear-type oil pump. This pump takes suction through a screen from an oil pan or sump. From the pump, the oil is forced through the oil strainer and the oil cooler into the main oil gallery. This gallery extends the length of the engine and serves as a passage and reservoir from which the oil is fed to the main bearings.

Constant oil pressure, throughout a wide range of engine speeds, is maintained by the pressure relief valve that allows the excess oil to flow back into the sump. All of the oil from the pump passes through the strainer, unless the oil is cold and heavy, or the strainer (or oil cooler) is clogged. In such cases, the bypass valve is forced open and the oil flows directly to the engine. Part of the oil fed to the engine is returned through the filter, which removes flakes of metal, carbon particles, and other impurities.

COOLING SYSTEM

Diesel engines are equipped with a water-cooling system to carry away the excess heat produced in the engine cylinders. The water is circulated through water jackets in the cylinder walls and passages that surround the valves in the cylinder head.

Either fresh water or sea water may be used for cooling. In some engines the sea water is circulated through the engine and then discharged overboard. In other types, fresh water is circulated through the engine and then through a heat exchanger. Sea water is circulated through this exchanger and cools the fresh water. An advantage of the fresh water system is that it keeps the water passages cleaner and thus provides better cooling and allows the engine to operate at higher temperatures.

STARTING SYSTEM

The starting system of most small diesel engines follows the familiar gasoline engine design. It consists of a generator, an electric motor that serves as a starter, a suitable battery, and the necessary wiring. The generator keeps the battery charged and provides current for lights and other equipment. The charging rate of the generator is controlled by a voltage regulator, and a cut-out is provided to keep the battery from discharging through the generator at low speed.

When the starter button is pressed, the starter gear engages with the teeth on the flywheel and causes it to rotate; the rotary motion of the flywheel is transmitted to the crankshaft. Some diesel engines are started with compressed air or with a small auxiliary gasoline engine.

GASOLINE ENGINES

The main parts of the gasoline engine are quite similar to those of the diesel engine. The two engines differ principally in that the gasoline engine has a carburetor and an electrical ignition system.

The induction system of a gasoline engine draws gasoline from the fuel tank and air from the atmosphere, mixes them, and delivers the mixture to the cylinders. It consists of the fuel tank, the fuel pump, the carburetor, and the necessary fuel lines and air passages. Flexible copper tubing carries the fuel from the tank to the carburetor, while the intake manifold carries the fuel-air mixture from there to the individual cylinders. The fuel-air mixture is ignited by an electric spark.

The CARBURETOR is a device used for sending a fine spray of fuel into a moving stream of air as it moves to the intake valves of the cylinders. The spray is swept along, vaporized, and mixed (as a gas), with the moving air. The carburetor is designed to maintain the same mixture ratio over a wide range of engine speeds. The MIXTURE RATIO is the number of pounds of air mixed with each pound of gasoline vapor. A RICH MIXTURE is one in which the percentage of gasoline vapor is high, while a LEAN MIXTURE contains a low percentage of gasoline vapor.

The electrical system of the gasoline engine has the same units as the diesel engine, plus the ignition system. This system is designed to deliver a spark in the combustion chamber of each cylinder at a specific point in that cylinder's cycle of operation. A typical ignition system includes a storage battery, an ignition coil, breaker points, a condenser, a distributor, a spark plug in each cylinder, a switch, and the necessary wiring. (See fig. 12-8.)

There are two distinct circuits in the ignition system, called the primary and secondary. The

9483

Figure 12-8.—Schematic wiring circuits of an ignition system.

primary circuit carries a low-voltage current, the secondary is a high-voltage circuit. The battery, the ignition switch, the ignition coil, and the breaker points are connected in the primary circuit. The secondary circuit, also connected to the ignition coil, includes the distributor and the spark plugs.

The STORAGE BATTERY is usually the 6- or 12-volt type. One terminal is grounded to the engine frame while the other is connected to the ignition system.

The IGNITION COIL is in many respects similar to an electromagnet. It consists of an iron core surrounded by the primary and secondary coils. The primary coil is made up of a few turns of heavy wire, while the secondary coil has a great many turns of fine wire. In both coils, the wire is insulated, and the coils are entirely separate from each other.

The BREAKER POINTS constitute a mechanical switch connected in the primary circuit. They are opened by a cam that is timed to break the circuit at the exact instant at which each cylinder is due to fire. A condenser is connected across the breaker points to prevent arcing and to provide a better high-voltage spark.

The DISTRIBUTOR, connected to the secondary or high-voltage circuit, serves as a selector switch that channels electric current to the individual cylinders. Although the breaker points are connected in the primary circuit, they are often located in the distributor case. The same drive shaft operates both the breaker points and the distributor.

The SPARK PLUGS, which extend into the combustion chambers of the cylinders, are connected by heavy insulated wires to the distributor. (See fig. 12-9.) A spark plug consists essentially of a metal shell that screws into the spark plug hole in the cylinder, a center electrode embedded in a porcelain cylinder, and a side electrode connected to the shell. The side electrode is adjusted so that the space between it and the center electrode is about 0.025 inch. When the plug fires, an electric spark jumps across this gap between the electrodes.

When the engine is running, the electric current in the primary circuit flows from the battery through the switch, the primary winding in the ignition coil, the breaker points, and then back to the battery. The high voltage is produced in the secondary winding in the ignition coil and flows

68A9484

77.158

Figure 12-9.—Sectional view of a typical spark plug.

through the distributor to the individual spark plugs and back to the ignition coil through the engine frame. It is interesting to note that the high voltage, which jumps the gap in the spark plugs, does not come from the battery but is produced in the ignition coil. (See fig. 12-8.)

The ignition coil and the condenser are the only parts of the ignition system that require an explanation. The soft iron core and the primary winding function as an electromagnet. The current flowing through the primary winding magnetizes the core. This same core and the secondary winding function as a transformer. Variations in the primary current change the magnetism of the core, which in turn produces high voltage in the secondary winding.

With the engine running and the breaker points closed, a low-voltage current flows through the primary circuit. When the breaker points open, this current is interrupted; this produces a high voltage in the secondary circuit. The electricity that would otherwise arc across the breaker points as they are separating, now flows into the condenser.

The principal purpose of the condenser is to protect the breaker points from being burned. The condenser also aids in obtaining a hotter spark.

The starting system of the gasoline engine is basically the same as that of the diesel engine. The generator keeps the battery charged and provides the current to operate the lights and other electrical equipment. The starter motor draws current from the battery and rotates the flywheel and crankshaft for starting.

The electrical system usually requires about 90 percent of the routine maintenance performed on gasoline engines. You should keep the connections tightened and the battery terminals covered with a light coating of petrolatum. Unsatisfactory operation can usually be traced to either dirty fuel or fouled spark plugs. Straining the fuel before it is put in the tank, and filling the tank each time the engine is secured would eliminate most of the fuel difficulties. A fouled plug can be removed and cleaned by wire brushing or sand blasting.

GAS TURBINE ENGINES

Until recently, the application of the gas turbine engine to marine use in the Navy has been experimental. Experiments have proved that the gas turbine engine can be used to power short-range ships, landing craft, high-speed craft such as PT and air-sea rescue boats, emergency generators, and portable firefighting equipment. The MSB-5 class minesweepers were the first U.S. naval ships to use gas turbine engines on an operational basis. Gas turbine installations aboard the MSB-5 class minesweepers supply power for the generators. Two gas turbine engines drive the generator through a combining reduction gear (see fig. 12-10). The output shafts of the engines are connected to the combining reduction gear by flexible couplings and overrunning clutches.

Additional marine applications of the gas turbine engine have been made on an operational basis; as service experience has been gained, the number of gas turbines in use has increased. Since both the number of installations and service experiences are limited at present, the following discussion deals with a comparison of gas turbines and reciprocating engines, the advantages and disadvantages of the gas turbine as a marine power plant, and the terminology and operating principles of gas turbine engines and their principal parts, or components.

COMPARISON OF GAS TURBINES AND RECIPROCATING ENGINES

The gas turbine is similar to reciprocating engines in that air is compressed, a fuel-air mixture is burned, and the gases of combustion are expanded to produce useful power. Engines

9485

comparable application. The gas turbine adjusts to varying loads more rapidly than other type engines.

The number of personnel required to operate and maintain a gas turbine engine, and the time required for the training of such personnel are much less than for engines of other types. Only one man is needed for starting and operating some gas turbine engines. The simplicity of the operating controls and the automatic safety devices used reduce the time required for training operators.

Compared to a diesel engine, the gas turbine has far fewer components and produces much less vibration at full power. The gas turbine engine has a significant advantage over the gasoline engine in the fuel used. The fuel used in gas turbines presents much less of a fire hazard than the highly volatile fuel used in gasoline engines.

Even though the gas turbine engine has some advantages over other types of internal combustion engines, it also has some disadvantages such as a higher rate of fuel consumption and larger components required for air inlet and exhaust.

COMPONENTS OF GAS TURBINE ENGINES

The gas turbine engine uses processes in its operation which are similar to those employed in other types of internal combustion engines. The engine components and the terms used to identify them are considerably different from the parts and terms which are common to the diesel and gasoline engines. The terms defined here and the operating principles and components discussed later are applicable to Boeing 502 two-stage engines. Although gas turbine engines vary in design and Navy installations include engines of other manufacturers, much of the discussion in the following section is applicable to all gas turbine engines.

The components of a gas turbine engine may be grouped as (1) parts of the basic engine, (2) engine accessories, and (3) engine systems. Figure 12-11 shows a 2-stage Boeing 502 engine.

Parts of the Basic Engine

The forward (compressor end) section of the engine, where a stream of hot expandable gases is created as a result of continuous compression and combustion, is called the gas producing section. This section consists principally of the compressor, burners, and first stage turbine wheel.

The COMPRESSOR is that part of the engine which draws in air and compresses it by centrifugal force (that force which tends to move something outward from a center of rotation). The compressor consists of a rotating impeller (a

Figure 12-11.—Schematic illustration of a 2-stage gas turbine (Boeing 502).

9487

vaned disk) enclosed by a case which has diffusing vanes on its inner surface. The BURNER is that part of the engine in which combustion occurs. It consists of a cylindrical outer shell, perforated inner liner, fuel nozzle, and igniter plug. A metal chamber that collects combustion gases from the burners and directs them, through fixed vanes or nozzles, is called the NOZZLE BOX. The rotating assembly, consisting of the compressor impeller, an interconnecting shaft, and first stage turbine wheel, is called the ROTOR.

The section of the engine which changes energy into useful power is known as the power output section. The main parts of this section are the second stage turbine wheel, exhaust ducts, reduction gear, and output shaft.

The TURBINE WHEEL is a bladed disk which turns when the exhaust gas stream acts upon its blades. A circular metal duct, containing a ring of fixed vanes that form nozzles, which directs the gas flow from the first-stage turbine to the second-stage turbine is called the INTERSTAGE BLEED ASSEMBLY. The assembly also provides a means of releasing some of the combustion gases to the exhaust duct ahead of the second-stage turbine. A WASTE GATE (gate-type valve) in the interstage bleed duct controls the escape of combustion gases ahead of the second-stage turbine. An EXHAUST DAMPER (gate-type valve), in the turbine exhaust duct, controls the escape of gases aft of the second-stage turbine.

Engine Accessories

The main engine components discussed to this point are not the only ones required to make a complete engine. Like other types of internal combustion engines, the gas turbine engine includes various accessories.

The parts which constitute the engine accessory group are driven by the engine rotor or by the output shaft. The rotor-driven accessories include the gear-type FUEL PUMP, centrifugal fuel control GOVERNOR, and vane-type combination pressure-scavenge OIL PUMP. A centrifugal OVERSPEED SWITCH is driven by the output shaft.

Engine Systems

The principal systems of a gas turbine engine are those which supply fuel for combustion, oil for lubrication, and electricity or air for starting the engine and the operation of instruments and warning and safety devices. The engine accessories are usually considered as components of whichever system they affect.

OPERATION OF SMALL BOAT ENGINES

When a ship is at anchor, the officers and crew travel to and from the shore in small boats. As a Fireman, you may be assigned as an engineer on one of these small craft. A coxswain will be in charge of the boat. In some boats there may also be two seamen acting as bow and stern hooks.

You will be responsible for operating the boat's engine. You will receive your orders from the coxswain over the boat's bell system. You should know the bell signals; two sounds for neutral, one for slow ahead, three for reverse, and four calls for full speed in the direction in which you are going. The coxswain will expect you to comply with the bells instantly.

DIESEL-POWERED BOAT OPERATION

The actual operation of a small boat diesel might be considered as consisting merely of starting it, regulating the speed, and stopping it. However, there are other factors which should be considered. If you are going to depend on the engine to give reliable service, you must give it a lot of attention. Your first experience in getting stuck halfway between the ship and dock may leave a lasting impression on you, particularly if you happen to have the captain aboard.

When you are assigned to a boat, your first responsibility consists of inspecting the engine and warming it up. You should check the fuel supply, the lubricating oil, and the cooling system. When you are satisfied that everything is as it should be, you are ready to start the engine.

Starting a diesel engine ordinarily consists of CRACKING THE THROTTLE, or opening it part way, and pressing the starter button. The engine should start after the starter has turned it over a couple of times. It should be warmed up by running it at low speed until it is up to operating temperature.

While the engine is warming up, you will have a chance to find out whether or not it is in good running condition. Watching the instrument panel will help you determine the condition of the engine. (See fig. 12-12.) For example, if the oil gage fails to register any pressure, you should stop the engine immediately. The water temperature gage is used as an indirect indication of the temperature of the engine parts. The engine exhaust is usually cooled by sea

9488

139.48

Figure 12-12.—The instrument panel of a small diesel-powered boat.

water; the exhaust discharge should be inspected immediately after starting to determine if the water pump has suction. If the pump does not have suction, stop the engine and check the cooling system for such troubles as a clogged strainer and closed sea valves. You should check the idling speed by bringing the throttle back to the idling position. The engine should respond normally to changes in the throttle setting, and it should run smoothly after being brought up to operating temperature.

You should know where the fuel- and lube-oil strainer drains are located, so that you can get rid of any water that may accumulate in these systems. If lube oil must be added, see that the proper grade approved for that particular engine is used.

The engine can be stopped by merely closing the throttle. You should leave the engine compartment clean and orderly. A report calling attention to any abnormal operating condition that you may have noticed will be a help to the maintenance and servicing crew.

Another important part of your job is TROUBLESHOOTING. Diesel engine failure can usually be attributed either to the fuel system or to improper cooling or lubrication. If the fuel is not reaching the engine cylinders, you can often trace the trouble to an empty fuel tank or an accumulation of water in the strainers. A plugged vent in the fuel tank filler cap will cause a vacuum to form in the top of the tank, and the engine will stop for want of fuel. Overheating generally results from a lack of either oil or cooling water.

GASOLINE ENGINE OPERATION

The operation of a small boat gasoline engine is similar to that of a diesel engine. Since gasoline from a leak or an open container will vaporize quickly and may form an explosive mixture, additional precautions against fire must be taken. Adequate ventilation must be provided to rid the engine compartment of any combustable vapors which may accumulate. No smoking is permitted in small boats at any time, this is especially important in boats equipped with gasoline engines.

More gasoline engines stop because of ignition trouble than for any other reason. Defects in the ignition system can usually be detected by either hard starting or irregular firing of the cylinders. Hard starting can generally be traced to dirty and pitted breaker points, or too wide a gap between the points. A missing cylinder can usually be corrected by cleaning the faulty spark plug.

9489

CHAPTER 13

ENGINEERING WATCHES

Throughout the chapters of this training course you have become acquainted with the organization and ratings of the engineering department. You may be assigned to one of many different types of ships. On these ships you will find that the engineering spaces will vary in size and appearance. If you are assigned to a steam-driven ship, you may find the boilers, the main engines, and their associated equipment in one space; or you may find the boilers and their equipment in one space, and the main engines and their equipment in another space. Regardless of the number of boilers and main engines, many of the watches are basically the same. Therefore the information in this chapter is general in nature and does not apply strictly to any one ship.

This chapter contains information related to some of the watches and the duties that you will be required to perform, such as messenger of the watch, sounding and security watch, and cold-iron watch. As you progress and become acquainted with the fireroom or engineroom you will be required to stand other watches under the supervision and instruction of a petty officer. These watches include: (1) for the fireroom, burnerman, blowerman, and checkman and (2) for the engineroom, lower level watch, upper level watch, evaporator watch, shaft alley watch, and throttle watch.

MESSENGER OF THE WATCH

The messenger of the watch performs a number of important duties that involve a great deal of responsibility. The messenger is usually assigned as telephone talker on the engineering JV circuit, during close maneuvering conditions with other ships, when entering or leaving port, or when refueling or replenishing from another ship. Because the JV circuit is used to provide communications between all the engineering spaces, you must know proper telephone procedures; when you talk, speak slowly and in a very distinct manner pronouncing the syllables of each word very clearly. When you receive a message, or are given a message to transmit, be sure to repeat it word for word, exactly as it was given to you; do not engage in any idle chatter.

As the messenger on watch you will also perform such other duties as the petty officer of the watch may designate. This includes checking all operating machinery to see that it is operating properly, recording temperature and pressure readings in the appropriate logs, and calling the watch relief.

The operating log is an hourly record of operating pressures and temperatures of almost all operating machinery. The log readings include lube oil pressures and temperatures, boiler pressures and temperatures, pump suctions and discharge pressures, and other items of importance to the operation of the engineering plant. You should become acquainted with proper operating pressures and temperatures so that you will know when a piece of machinery or equipment is not operating properly.

SOUNDING AND SECURITY WATCH

As a Fireman, you will be required to stand sounding and security watches. While on this watch, your primary mission is to look for fire and flooding hazards. On most ships, this watch is stood from the end of the working day until 0800 the next morning and during holiday routine. The watch is particularly needed at these times because there are fewer personnel working aboard the ship and certain spaces that require frequent observation are not under the normal observation of personnel working in or near them. On some ships (particularly the larger ones), sounding and security watches are stood around the clock. In addition to looking for fire and flooding hazards, be sure no fresh water spigots are leaking or left running in heads, washrooms, galleys, and pantries. Another of your responsibilities while on watch is to maintain the proper condition

1089490

of material readiness by checking all watertight air ports, doors, hatches, scuttles, and all other damage control fittings. Report any irregular condition (change in soundings, violations of material condition, fire hazards, etc.) to the officer of the deck.

SOUNDINGS

A sounding tube is usually made of 1 1/2-inch pipe. The lower end is fitted at a low point in the compartment, tank, or void which the tube serves. The upper end terminates in a flush deck plate which is usually located on the main or second deck; it is closed with a threaded plug or cap.

Tubes are made as straight as possible, but some are necessarily curved. Some sounding tubes, particularly those serving spaces under the enginerooms and firerooms, cannot be extended to the upper decks because of the construction of the ship. These tubes terminate in risers which extend approximately 3 feet above the compartment served; they have gate valve closures.

Soundings are taken with a sounding rod or sounding tape, whichever is provided for that purpose aboard ship. The sounding rod is normally about 6 feet long and is made of 12-inch lengths of 1/2-inch brass or bronze rods. It is lowered with a chain or line. The sounding tape is a steel tape, coiled on a reel suitable for holding while the tape is lowered. The tape is weighted at the end to facilitate lowering into the sounding tube.

HOW TO TAKE A SOUNDING

Before you take a sounding, dry the rod or tape thoroughly and coat it with white chalk. Water is relatively hard to see on a brass or bronze sounding rod; however, when the chalk becomes wet, it turns to a distinctly visible light brown color. For example, if there is 6 inches of water in a tank whey you take a sounding, the light brown color of the chalk will be distinctly visible up to the 6-inch mark; while the remainder of the sounding rod will still be covered with the white chalk. The chalk method is used only where water may be present.

When the sounding rod has been coated with chalk, lower it down the tube until it touches the bottom; immediately draw it back. Do not drop the rod or tape to the bottom, but lower it slowly so that it hits bottom without injuring the rod or tape. If the ship is rolling, try to lower and hoist the rod or tape while the ship is on an even keel. After you have taken the sounding, enter the reading in the sounding log.

COLD-IRON WATCH

When a ship moves alongside a repair ship or a tender, or into a naval shipyard, and is receiving power from these activities, a security and fire watch is usually set by each department. This watch is commonly called the COLD-IRON WATCH.

Each cold-iron watch makes frequent inspections of the area assigned to him, and looks for fire hazards or other unusual conditions throughout the area. He sees that no unauthorized persons are in his watch area, that all spaces are cleaned, and that no tools, rags, gear, and the like are left adrift. He keeps bilges reasonably free of water.

The watch makes hourly reports to the officer of the deck as to all existing conditions. Any unusual conditions that do exist are reported to the officer of the deck immediately so that the department responsible can be notified to take the necessary corrective measures.

In the event that welding or burning is going on in his area, the cold-iron watch sees that a fire watch is stationed. (The fire watch stands by with a CO_2 extinguisher.) if none has been stationed, he should have the work discontinued until the fire watch has been stationed. The cold-iron watch carries out all orders and special orders pertaining to the duties of that watch.

If the ship is in drydock, the watch must check all sea valves after working hours, to see that the valves are secure or are blanked off. He must see that no oil is pumped into the drydocks at any time. He will not allow any weights, such as fuel oil, feed water, or potable water, to be shifted without permission of the engineer officer.

The cold-iron watch is required to be familiar with all regulations, instructions, and safety precautions and must see that these are observed. He gives his relief all information regarding existing conditions, orders, and special orders. If the relieving watch is not satisfied with the conditions, he will not relieve him, but will report for instructions to the petty officer with the day's duty.

BURNERMAN

The burnerman maintains proper steam pressure by cutting in or out burners, or by regulating the fuel oil pressure at the burners. The steam pressure must be held at the working pressure, and as steady as possible. The burnerman

0016491

must keep a close check for dirty atomizers, by observing their operation and condition of the fire. He changes the atomizers when authorized by the petty officer in charge of the watch.

The burnerman depends upon a steam pressure gage and a superheated steam temperature thermometer for information on conditions within the boiler. In most cases an engine order telegraph (annunciator) is located near the burner front so that the fireroom watch may know what main engine changes are being made.

As engine speed and steam conditions change, the burnerman must rapidly cut burners in or out as required to hold the steam pressure steady. During maneuvering in close contact with other ships, and when the ship is entering or leaving port, the burnerman must be constantly alert for large rapid changes in engine speed.

BLOWERMAN

The blowerman is responsible for operating the forced draft blowers that supply combustion air to the boiler. Although the air pressure in the double casings is affected by the number of registers in use and the extent to which each register is open, it is chiefly determined by the manner in which the forced draft blowers are operated. The opening, setting, or adjusting of the air registers is the BURNERMAN'S job. The control of forced draft blowers is the blowerman's job. It is important for the burnerman and the blowerman to cooperate with each other, since both are concerned with the combustion of the fuel oil.

CHECKMAN

The checkman is responsible for operating the feed stop valve and the feed check valve. The checkman has ONLY ONE JOB—that of maintaining the proper water level in the boiler. This job requires full attention at all times. When a boiler is being operated manually, the checkman must NEVER be given any other duties.

Some ships are equipped with fully automatic feed water controls. On these ships a checkman is not needed when the feed water is being controlled automatically. However if the automatic system fails or is swtiched to manual control, then a checkman must be immediately stationed on the checks.

THROTTLE WATCH

Being a throttleman at the main engines is a very important task. Orders from the bridge relative to movement of the propellers must be complied with immediately. To make correct adjustments for the required speed you have to keep a close watch on the rpm indicator on the throttle board, and open and close the throttle as required to attain or maintain the necessary rpm. In addition to handling the throttle itself, you may also have to operate various associated valves, accurately log all speed changes in the Engineer's Bell Book, visually check all gages (pressure, temperature, vacuum, etc.) installed on the throttle board, and keep the petty officer in charge informed of any abnormal gage readings.

You should become thoroughly familiar with all the gages, instruments, and indicators on the throttle board so that you will know what a normal reading is. There are steam pressure gages, steam temperature thermometers, a revolutions-per-minute (rpm) indicator, an engine order telegraph, feed water pressure gages, cooling water pressure gages, gages indicating the vacuum obtained in the main engine low pressure turbine, and others. Whenever an opportunity presents itself, study the throttle board and ask questions. Do not hesitate to ask the operator if those are normal readings and if they are the approximate readings you should always see there during steaming conditions. When you have learned the difference between a normal reading and an abnormal reading you may possibly help to prevent a major casualty by observing an abnormal reading and reporting it to the petty officer in charge of the watch.

LOWER LEVEL WATCHES

When you are assigned to the lower level to assist the lower level watch (pumpman) and to learn his duties and responsibilities, you will find a considerable number of pumps and other auxiliary machinery. Some of the pumps and equipment you will find are the main lube oil pumps and lube oil coolers, main condensate pumps and main condenser—and when installed in the engineroom—main feed pumps, main feed booster pumps, and fire pumps. In some installations you will also find air compressors on the lower level.

In addition to learning the proper procedures for starting, operating, and stopping the pumps and equipment, various routine checks must be made on the operating machinery. Some of the checks for the main feed pump, the lube oil pump, and the main condensate pump, are discussed in the sections that follow. Under the watchful

9492

eye of the pumpman you will learn how to make the following checks and perform the following duties.

MAIN FEED PUMP

In addition to complying with the posted instructions and safety precautions for the machinery and equipment at his station the pumpman performs the following duties:

1. Maintains main feed pump discharge pressure at a predetermined value by adjusting the constant pressure governor.
2. Keeps main feed pump bearings at the proper temperature by regulating the flow of water through the feed pump lube oil cooler.
3. Checks to ensure proper lube oil pressure to the bearings.
4. Keeps shaft packing glands adjusted properly. A small leakage is necessary for lubrication to prevent burning out the packing but an excessive amount of leakage wastes boiler feed water.
5. Checks and maintains proper lube oil level in the main feed pump sump tank.
6. Keeps valve packing glands tightened to prevent leakage.
7. Keeps his watch station clean; removes fire hazards by wiping up oil and picking up rags and other stray gear.
8. Is alert for unusual sounds, vibrations, temperatures, and pressures.
9. Keeps the standby pump ready for instant use.

LUBE OIL PUMP

1. Maintains the proper lube oil pump discharge pressure, by adjusting the constant pressure governor.
2. Keeps the standby pump on automatic standby, ready for instant use.
3. Shifts and cleans main lube oil strainers once a watch or more often if required.
4. Checks the lube oil system for leaks and maintains the proper oil level in the main engine sump tank.
5. Operates the lube oil purifier as ordered.
6. Checks the oil pressure to the lube oil service pump bearings and maintains the oil at the proper temperature by regulating the amount of water through the pump lube oil cooler.
7. Regulates the cooling water flow through the main lube oil cooler to maintain the correct oil outlet temperature.

MAIN CONDENSATE PUMP

1. Keeps the condensate in the condenser hot well at the proper level.
2. Frequently checks the exhaust trunk and main condenser overboard for abnormal temperatures.
3. Checks the main condensate pump bearings for proper oil pressure and temperature.
4. Keeps the main condenser vented.
5. Starts or secures an additional pump, as required, to keep the condensate level at the correct height.
6. Constantly checks for unusual conditions such as vibrations, sounds, and high or low temperatures or pressures.

All watchstanders should be constantly alert for signs of leakage in all parts of the steam and water systems. Some of the more common causes of feed water waste are as follows: (1) leaks in pipe fittings, flanges, valve and pump packing glands, pump housings and relief valves; (2) use of excessive gland sealing steam; and (3) failure to shift drains from the bilges to the appropriate drain system. Using an excessive amount of boiler feed water is an indication of a poorly operated plant and reflects on the ability of the watchstander.

UPPER LEVEL WATCH

When you are assigned to learn the duties of the upper level watch in the engineroom, you will record periodic temperature and pressure readings from the various gages on, or connected to, the upper level machinery; make required valve adjustments to correct conditions indicated by slight variations from the normal readings, and report unusual conditions to the petty officer in charge; maintain a normal water level in the deaerating tank, if it is in the engineroom, by adjustments of the excess and make-up feed valves; start and stop turbogenerators, and other upper level machinery, as ordered; and maintain an adequate gland seal pressure on the turbogenerator.

SHAFT ALLEY WATCH

Another main engine duty to which you may be assigned is that of keeping watch on the bearings of the propeller shafts leading from the reduction gears (or motors of a turbo-electric driven ship) to the ship's propellers. The SHAFT ALLEY WATCHSTANDER:

1. Checks all spring bearings for proper lubrication, including correct oil level, condition

of the oil, proper operation of self-oiling devices (ring or chain), and bearing temperature.

2. Checks and adjusts stern tube gland for correct amount of leak-off.

3. Is responsible for having the shaft alley bilge pumped.

4. Is to be especially alert during high speed to observe any abnormal rise in bearing temperature.

5. Reports hourly, by phone, to the control engineroom and at any time that abnormal conditions develop.

6. In ships which have the main thrust bearing in the shaft alley, is responsible for operation of the main thrust bearing lube oil system.

7. Performs any other additional duties which may be assigned.

EVAPORATOR WATCH

A ship requires a large amount of pure fresh water, daily, yet a ship can only store sufficient water to last a few days; therefore proper and careful watches must be maintained on the evaporators whenever they are in operation. Proper watchstanding requires the operator to constantly check pressures, temperatures, vacuum, and salt content of the distilled water. The ship cannot operate if the distilled water that is to be used for feed water contains more salt than the maximum allowable limits.

OTHER WATCHES OR ASSIGNMENTS

Each division officer prepares a Watch, Quarter, and Station Bill for his division. You will generally find the following information on this bill:

1. Organization of the division (i.e., sections and watches).

2. Listing of each man as to billet number, locker number, bunk number, compartment number, name, rating, and rate (actual and allowance).

3. Watch assignments for each man under various conditions of battle readiness.

4. Station each man will have and what he will provide for emergency situations such as Fire, Rescue and Assistance, and General Emergency.

5. Visit and search party, landing force, special sea detail, and other special duties and stations which each man is assigned.

The Watch, Quarter, and station Bill tells you where you fit into the ship's organizational picture: Check it frequently, for it is your duty to know where you belong under all conditions. There is NO EXCUSE FOR NOT KNOWING. The bills may be differently designed for different ships, but the stations and duties are always approximately the same.

9494

APPENDIX I

TRAINING FILM LIST

Certain training films that are directly related to the information presented in this training course are listed under the appropriate chapter numbers and titles. Unless otherwise specified, all films listed are black and white with sound, and are unclassified. For a description of these and other training films that may be of interest, see the United States Navy Film Catalog, NavPers 10000 (revised).

APPENDIX II

GLOSSARY—ENGINEERING TERMS

When a man enters a new occupation, he is faced with the necessity of learning the vocabulary of the trade in order to understand his fellow workmen, and make himself understood by them. Shipboard life requires that the Navyman learn a relatively new vocabulary—even new terms for many commonplace items. The reasons for this need are many, but most of them boil down to convenience and safety. Under certain circumstances, a word or a few words mean an exact thing or a certain sequence of actions, making it unnecessary to give a lot of explanatory details.

A great deal of the work of a Fireman is such that an incorrectly interpreted instruction could cause confusion, breakage of machinery, or even loss of life. Avoid this confusion and its attendant danger by learning the meaning of terms common to the Engineering Department.

This glossary is not all-inclusive, but it does contain many terms the meaning of which every Fireman should know. The terms given in this glossary may have more than one definition; only those definitions as related to engineering are given.

ABT (AUTOMATIC BUS TRANSFER): An automatic electrical device that supplies power to vital equipment. This device will shift from the normal power supply to an alternate power supply when the normal supply is interrupted.

ACETYLENE: A gas that is chemically produced from calcium carbide and water, used for welding and cutting.

ADAPTER: A coupling or similar device that permits fittings with different-sized openings (apertures) to be joined together.

AIR EJECTOR: A type of jet pump, used to remove air and other gases from the condensers.

AIR CHAMBER: A chamber, usually bulb-shaped, on the suction and discharge sides of a pump. Air in the chamber acts as a cushon and prevents sudden shocks to the pump.

AIR REGISTER: A device in the casing of a boiler, used for regulating the amount of air for combustion and to provide a circular motion to the air.

AISE: Association of Iron and Steel Engineers.

ALLOY: A mixture composed of two or more metals.

ALTERNATING CURRENT (A-C): Current that is constantly changing in value and direction at regular recurring intervals.

AMBIENT TEMPERATURE: The temperature of the surrounding area.

AMMETER: An instrument for measuring the rate of flow of electrical current in amperes.

ANNEALING: The softening of metal by heating and slow cooling.

ANNUNCIATOR: See ENGINE ORDER TELEGRAPH.

ARGON: An inert gas, slightly heavier than air, used in inert-gas shielded metal arc welding.

ARMORED CABLE: An electric cable that is protected on the outside by a metal covering.

ASTM: American Society for Testing Metals.

AUTOMATIC COMBUSTION CONTROL SYSTEM (ACC): A system that provides a means of automatically controlling the fuel and air mixture in a boiler.

BACK PRESSURE: The pressure exerted on the exhaust side of a pump or engine.

BDC (BOTTOM DEAD CENTER): The position of a reciprocating piston at its lowest point of travel.

BALLASTING: The process of filling empty tanks with salt water, to protect the ship from underwater damage and increase its stability. See DEBALLASTING.

9498

BLUEPRINTS: Reproduced copies of drawings (usually having white lines on a blue background.

BOILER: A strong metal tank or vessel composed of tubes, drums, and headers, in which water is heated by the gases of combustion to form steam.

BOILER CENTRAL CONTROL STATION: A centrally located station for directing the control of all boilers in the fireroom.

BOILER DESIGN PRESSURE: Pressure specified by the manufacturer, usually about 103% of normal steam drum operating pressure.

BOILER INTERNAL FITTINGS: All parts inside the boiler which control the flow of steam and water.

BOILER OPERATING PRESSURE: The pressure required to be maintained in a boiler while in service.

BOILER OPERATING STATION: A location from which boilers are operated.

BOILER RECORD SHEET: A NavShips form maintained for each boiler, which serves as a monthly summary of operation.

BOILER REFRACTORIES: Materials used in the boiler furnace to protect the boiler from heat of combustion.

BOILER ROOM: A compartment containing boilers but not containing a station for operating or firing the boilers. Refers specifically to bulkhead enclosed boiler installations.

BOILER TUBE CLEANER: A CYLINDRICAL brush that is used to clean the insides of boiler tubes.

BOILER WATER: Refers to the water actually contained in the boiler.

BRAZING: A method of joining two metals at high temperature with a molten alloy.

BRINE: A highly concentrated solution of salt in water, normally associated with the overboard discharge of distilling plants.

BRITTLENESS: That property of a material which causes it to fracture prior to any noticeable signs of deformation.

BURNERMAN: Man in fireroom who tends the burners in the boilers.

BUSHING: A renewable lining for a hole through which a moving part passes.

BYPASS: To divert the flow of gas or liquid. Also, the line that diverts the flow.

CALIBRATION: The comparison of any measuring instrument with a set standard.

CANTILEVER: A projecting arm or beam supported only at one end.

CAPILLARY TUBE: A slender thin-walled small-bored tube used with remote-reading indicators.

CARBON DIOXIDE: A colorless, orderless gas used as a fire extinguishing agent and for inflating liferafts and lifejackets.

CARBON PACKING: Pressed segments of graphite used to prevent steam leakage around shafts.

CASUALTY POWER SYSTEM: A means of using portable cables to transmit power to vital equipment in an emergency.

CHECK VALVE: A valve that permits a flow of liquid in one direction only.

CHILL SHOCKING: A method of removing scale from the tubes of a distilling plant, utilizing steam and cold water.

CHLORINE: A heavy gas, greenish-yellow in color used for water purification, sewage disposal, and in the preparation of bleaching solutions. Poisonous in concentrated form.

CIRCUIT BREAKER: An electrical device that provides circuit overload protection.

CLUTCH: A form of coupling which is designed to connect or disconnect a driving or driven member.

COMPARTMENT CHECKOFF LIST: A list of all damage control fittings, their location, and status for different ship conditions.

CONDENSER: A heat transfer device in which steam or vapor is condensed to water.

CONDUCTION: A method of heat transfer from one body to another when the two bodies are in physical contact.

CONSTANT PRESSURE GOVERNOR: A device that maintains a constant pump discharge pressure under varying loads.

CONTROLLER: A device used to stop, start, and protect motors from overloads, while they are running.

CORROSION: The process of being eaten away gradually by chemical action, such as rusting.

COUNTERSINK: A cone-shaped tool used to enlarge and bevel one end of a drilled hole.

CROSS-CONNECTED PLANT: A method of operating two or more plants as one unit, having a common steam supply.

CURTIS STAGE: A velocity-compounded impulse turbine stage having one pressure drop in the nozzles and two velocity drops in the blading.

DEAERATING FEED TANK (DA TANK): A unit in the steam-water cycle used to (1) free the condensate of dissolved oxygen, (2) heat the feed water, and (3) act as a reservoir for feed water.

DEBALLASTING: The process of emptying salt from tanks, to protect the ship from underwater damage and increase its stability.

DEGREE OF SUPERHEAT: The amount by which the temperature of steam exceeds saturation temperature.

DIATOMACEOUS EARTH: A light, crumbly silica material derived from algae and microscopic skeletons. It has relatively high absorption and filtering qualities.

DIATOMITE FILTERS: Filters made of a diatomaceous earth and asbestos filler.

DIRECT CURRENT (D-C): Current that moves in one direction only.

DIRECT DRIVE: One in which the drive mechanism is coupled directly to the driven member.

DISTILLATE: Fresh water produced in distilling plants.

DISTILLING PLANTS: Units commonly called evaporators (evaps) used to convert sea water into fresh water.

DRAWING: The plans used to show the fabrication and assembly details.

DRUM, STEAM: The large tank at the top of the boiler in which the steam collects.

DRUM, WATER: A tank at the bottom of a boiler; also called MUD DRUM.

DRY PIPE: A perforated pipe at the highest point in a steam drum to collect steam.

DUCTILITY: Property possessed by metals that allows them to be drawn or stretched.

ECONOMIZER: A heat transfer device on a boiler that uses the gases of combustion to preheat the feed water.

EDUCTOR: A jet type pump (no moving parts) used to empty flooded spaces.

EFFICIENCY: The ratio of the output to the input.

ELASTICITY: The ability of a material to return to its original size and shape.

ELECTRODE: A metallic rod (welding rod) used in electric welding that melts when current is passed through it.

ELECTROHYDRAULIC STEERING: A system having a motor-driven hydraulic pump that creates the force needed to actuate the rams to position the ship's rudder.

ELECTROLYSIS: A chemical action that takes place between unlike metals in systems using salt water.

ELECTROMOTIVE FORCE (EMF): A force that causes electrons to move through a closed circuit; expressed in volts.

ELEMENT: A substance which consists of chemically united atoms of one kind.

ENERGY: The capacity for doing work.

ENGINEER'S BELL BOOK: A legal record maintained by the throttle watch of all ordered main engine speed changes.

ENGINE ORDER TELEGRAPH: A device on the ship's bridge to give orders to the engineroom. Also called ANNUNCIATOR.

EPM (EQUIVALENTS PER MILLION): The number of equivalent parts of a substance per million parts of another substance. The word "equivalent" refers to the equivalent weight of a substance.

EXPANSION JOINT: A junction which allows for expansion and contraction.

FATIGUE: The tendency of a material to break under repeated strain.

FEED HEATER: A heat transfer device used to heat the feed water before it goes to the boiler.

FEED WATER: Fresh water, with the highest possible level of purity, made in EVAPORATORS for use in boilers.

FERROUS METAL: Metal with a high iron content.

FIREBOX: The section of a ship's boiler where fuel oil combustion takes place.

FIREMAIN: The salt water line that provides firefighting and flushing water throughout the ship.

FIRE TUBE BOILER: Boilers in which the gases of combustion pass through the tubes and heat the water surrounding them.

FLAREBACK: A backfire of flame and hot gases into a ship's fireroom from the firebox. Caused by a fuel oil explosion in the firebox.

FLASH POINT OF OIL: That temperature at which the oil vapor will flash into fire but the main body of the oil will not ignite.

FLEXIBLE I-BEAM: An I-shaped steel beam on which the forward end of a turbine is mounted; it allows for longitudinal expansion and contraction.

FLOOR PLATES: The removable deck plating of a fireroom or engineroom aboard ship.

FLUX: A chemical agent that retards oxidation of the surface, removes oxides already present, and aids fusion.

FORCE: Anything that tends to produce or modify motion.

FORCED DRAFT: A term used to describe air under pressure supplied to the burners in a ship's boiler.

FORCED DRAFT BLOWERS: Turbine-driven fans which supply air to the boiler furnace.

FORCED FEED LUBRICATION: A lubrication system that uses a pump to maintain a constant pressure.

9500

FORGING: The forming of metal by heating and hammering.

FRESH WATER SYSTEM: A piping system which supplies fresh water throughout the ship.

FUEL OIL MICROMETER VALVE: A valve installed at the burner manifold, which is used to control the fuel oil pressure to the burners.

FUEL OIL SERVICE TANKS: Tanks from which the fuel oil service pumps take suction for discharging oil to the burners.

FUSE: A protective device that is designed to open a circuit if the current flow exceeds a predetermined value.

GAGE GLASS: A device for indicating the liquid level in a tank.

GAS-FREE: A term used to describe a space that has been tested and found safe for hot work (welding & cutting).

GEARED-TURBINE DRIVE: A turbine that drives a pump, generator, or other machinery through reduction gears.

GROUNDED PLUG: A three pronged electrical plug used for grounding portable tools to the ship's structure. It is a safety device which always must be checked prior to using portable tools.

HAGEVAP SOLUTION: A chemical compound used in distilling plants, to prevent the formation of scale.

HALIDE LEAK DETECTOR: A device that is used to locate leaks in refrigeration systems.

HANDHOLE: An opening that is large enough for the hand and arm to enter the boiler for making slight repairs, and for inspection.

HANDY BILLY: A small portable water pump.

HARDENING: The heating and rapid cooling (quenching) of metal to induce hardness.

HARDNESS: The ability of a material to resist penetration.

HEAT EXCHANGER: Any device that is designed to allow the transfer of heat from one fluid (liquid or gas) to another.

HYDROGEN: A highly explosive, light, invisible, non-poisonous gas used for underwater welding and cutting operations.

HYDROMETER: An instrument used for determining the specific gravity of liquids.

HYDROSTATIC TEST: A pressure test using water to detect leaks in a boiler or other closed systems.

IGNITION, COMPRESSION: Ignition where the heat generated by compression in an internal combustion engine ignites the fuel (as in a diesel engine).

IGNITION, SPARK: Ignition where the mixture of air and fuel in an internal combustion engine is ignited by an electric spark (as in a gasoline engine).

IMPELLER: An encased, rotating element provided with vanes which draw in fluid at the center and expel it at a high velocity at the outer edge.

IMPULSE TURBINE: A turbine in which the major part of the driving force is received from the impulse of incoming steam.

INDIRECT DRIVE: A drive mechanism coupled to the driven member by gears or belts.

INERT: Inactive.

INJECTOR: A device which, by means of a jet of steam, forces water into the boiler, or as in the diesel engine—forces fuel into the cylinders.

INSULATION: A material used to retard heat transfer.

JACKBOX: Receptacle, usually secured to a bulkhead, in which telephone jacks are mounted.

JOB ORDER: The order issued by a repair activity to its own subdivisions, to perform a repair job in response to a WORK REQUEST.

JUMPER: Any connecting pipe, hose, or wire, normally for use in emergencies aboard ship, used to bypass damaged sections of a pipe, a hose, or a wire. (See BYPASS.)

JURY RIG: Any temporary or makeshift device.

LABYRINTH PACKING: Rows of metallic strips or fins used to prevent steam leakage along the shaft or a turbine.

LAGGING: A protective and confining cover placed over insulating material.

LIGHT OFF: Start, literally; "to start a fire in," as in "light off a boiler."

LOG BOOK: Any chronological record of events, such as an engineering watch log.

LOG, ENGINEERING: A legal record of important events and data concerning the machinery of a ship.

LOG ROOM: Engineer's office on board ship.

LUBE OIL PURIFIER: A unit that removes water and sediment from lubricating oil by centrifugal force.

MACHINABILITY: The term used to describe the ease with which a metal may be turned, planed, milled, or otherwise shaped.

MAIN CONDENSER: A heat exchanger which converts exhaust steam to feed water.

MAIN DRAIN SYSTEM: The system used for pumping bilges, consisting of pumps and associated piping.

MAKEUP FEED: Water of required purity intended for use in ship's boilers. It is the water needed to replace that lost in the steam cycle.

0050 9501

MALLEABILITY: That property of a material which enables it to be stamped, hammered, or rolled into thin sheets.

MANIFOLD: A fitting with numerous branches used to convey fluids between a large pipe and several smaller pipes.

MECHANICAL ADVANTAGE (MA): The advantage (leverage) gained by the use of such devices as a wheel to open a large valve, chain falls and block and tackle to lift heavy weights, and wrenches to tighten nuts on bolts.

MECHANICAL CLEANING: A method of cleaning the firesides of boilers by scraping and wire-brushing.

MICROMHOS: Electrical units used with salinity indicators for measuring the conductivity of water.

MOTOR GENERATOR SET: A machine which consists of a motor mechanically coupled to a generator and usually mounted on the same base.

NAVY BOILER COMPOUND: A powdered chemical mixture used in boiler water treatment to convert scale-forming salts into sludge.

NAVY SPECIAL FUEL OIL (NSFO): The name applied to the grade of fuel oil that the Navy uses in combatant ships.

NIGHT ORDER BOOK: A notebook containing standing and special instructions by the engineer officer to the night engineering officer of the watch.

NITROGEN: An inert gas which will not support life or combustion. Used in recoil systems and other spaces requiring an inert atmosphere.

NONFERROUS METAL: Metals that are composed primarily of some element or elements other than iron.

OFFICER OF THE WATCH (OOW): Officer on duty in the engineering spaces.

OIL KING: A petty officer who receives, transfers, discharges, and tests fuel oil and maintains fuel oil records.

OIL POLLUTION ACTS: The Oil Pollution Act of 1924 (as amended) and the Oil Pollution Act of 1961 prohibit the overboard discharge of oil and water containing oil in port, in any sea area within 50 miles of land, and in special prohibited zones.

ORIFICE: A small opening.

OVERLOAD RELAY: An electrical protective device which automatically trips when a circuit draws excessive current.

OXIDATION: The process of various elements and compounds combining with oxygen. The corrosion of metals is generally a form of oxidation; rust on iron, for example, is iron oxide or oxidation.

PANT, PANTING: A series of pulsations caused by minor, recurrent explosions in the firebox of a ship's boiler. Usually caused by a shortage of air.

PERIPHERY: The curved line which forms the boundary of a circle (circumference), ellipse, or similar figure.

PITOMETER LOG: Device for indicating speed of ship and distance traveled by measuring water pressure on a tube projected outside the ship's hull.

PLASTICITY: That property which enables a material to be excessively and permanently deformed without breaking.

PNEUMERCATOR: A type of manometer used for measuring the volume of liquid in tanks.

PPM (PARTS PER MILLION): A comparison of the number of parts of a substance in a million parts of another substance. Used to measure the salt content of water.

PREHEATING: The application of heat to the base metal prior to a welding or cutting operation.

PRIME MOVER: The source of motion as a turbine, automobile engine, etc.

PUNCHING TUBES: The name applied to the mechanical means of cleaning the interiors of boiler tubes.

RADIATION, HEAT: The process of emitting heat in the form of heat waves.

REACH RODS: A length of pipe or back stock used as an extension on valve stems.

REACTION TURBINE: A turbine in which the major part of the driving force is received from the reactive force of steam leaving the blading.

REDUCER: Any coupling or fitting which connects a large opening to a smaller pipe or hose.

REDUCING VALVES: Automatic valves which are used to provide a steady pressure lower than the supply pressure.

REDUCTION GEAR: A set of gears used to transmit the rotation of one shaft to another at a slower speed.

REEFER: A provision cargo ship or a refrigerated compartment. An authorized abbreviation for refrigerator.

REFRIGERANT 12 (R-12): A nonpoisonous gas that is used in air conditioning and refrigeration systems.

REGULATOR (GAS): An instrument used to control the flow of gases from compressed gas cylinders.

E0269502

REMOTE OPERATING GEAR: Flexible cables attached to valve wheels which permit the valves to be operated from another compartment.

RISER: A vertical pipe leading off a larger one; e.g., fireman riser.

ROOT VALVE: A valve located where a branch line comes off the main line.

ROTARY SWITCH: An electrical switch which closes or opens the circuit by a rotating motion.

SAE: Society of Automotive Engineers.

SAFETY VALVES: An automatic, quick opening and closing valve which has a reseat pressure lower than the lift pressure.

SALINOMETER: A hydrometer that measures the concentration of salt in a solution.

SATURATION PRESSURE: The pressure corresponding to the saturation temperature.

SATURATION TEMPERATURE: The temperature at which a liquid boils under a given pressure. For any given saturation temperature there is a corresponding saturation pressure.

SCALE: Undesirable deposit, mostly calcium sulfate, which forms in the tubes of boilers.

SENTINEL VALVES: Small relief valves used primarily as a warning device.

SHAFT ALLEY: The long compartment of a ship in which the propeller shafts revolve.

SKETCH: A rough drawing indicating major features of an object to be constructed.

SLIDING FEET: A mounting for turbines and boilers to allow for expansion and contraction.

SLUDGE: The sediment left in fuel oil tanks.

SOLID COUPLING: A device used to join two shafts rigidly.

SOOT BLOWER: A soot removal device using a steam jet to clean the firesides of a boiler.

SPECIFIC HEAT: The amount of heat required to raise the temperature of one gram of a substance 1°C. All substances are compared to water which has a specific heat of 1.

SPEED-LIMITING GOVERNOR: A device for limiting the rotational speed of a prime mover.

SPEED-REGULATING GOVERNOR: A device that maintains a constant speed on a piece of machinery that is operating under varying load conditions.

SPLIT PLANT: A method of operating propulsion plants so that they are divided into two or more separate and complete units.

SPRING BEARINGS: Bearings positioned at various intervals along a propulsion shaft to help keep it in alignment and support its weight.

SPRINKLING SYSTEM: An automatic watering system used for cooling and flooding magazines and cargo spaces in case of fire.

STATIC: A force exerted by reason of weight alone, related to bodies at rest or in balance.

STEAM LANCE: A device for using low pressure steam inside of boilers to remove soot and carbon from boiler tubes.

STEERING ENGINE: The machinery that turns the rudder.

STERN TUBE: A watertight enclosure for the propeller shaft.

STRAIN: The deformation or change in shape of a material resulting from the applied load.

STRENGTH: The ability of a material to resist strain.

STRESS: Force producing or tending to produce deformation of a metal.

STUFFING BOX: A device to prevent leakage between a moving and a fixed part in a steam engineering plant.

STUFFING TUBE: A packed tube making a watertight fitting through a bulkhead for a cable or small pipe.

SUMP: A container, compartment, or reservoir; used as a drain or receptacle for fluids.

SUPERHEATER: A unit in the boiler that drys the steam and raises its temperature.

SWASH PLATES: Metal plates in the lower part of the steam drum that prevent the surging of boiler water with the motion of the ship.

SWITCHBOARD: A panel or group of panels with automatic protective devices, used to distribute the electrical power throughout the ship.

TANK TOP: Top side of tank section or double bottom of a ship.

TDC (TOP DEAD CENTER): The position of a reciprocating piston at its uppermost point of travel.

TEMPERING: The heating and controlled cooling of a metal to produce the desired hardness.

THIEF SAMPLE: A sample of oil or water taken from a ship's tank for analysis.

THROTTLEMAN: Man in the engineroom who operates the throttles to control the main engines.

THRUST BEARING: A bearing designed to limit the end play and absorb the axial thrust of a shaft.

TO BLOW TUBES: A procedure, using steam, for removing soot and carbon from the tubes of steaming boilers.

TOP OFF: To fill up, as a ship tops off in fuel oil before leaving port.

9503

TOUGHNESS: That property of a material which enables it to withstand shock, and to be deformed without breaking.

TRANSFORMER: An electrical device used to step up or step down an a-c voltage.

TRICK WHEEL: A steering wheel in the steering engineroom or emergency steering station of a ship.

TUBE EXPANDER: A tool used to expand replacement tubes into their seats in boiler drums and headers.

TURBINE: A multibladed rotor, driven by steam or hot gas.

TURBINE JACKING GEAR: A motor-driven gear arrangement used to slowly rotate idle propulsion shafts and turbines.

TURBINE STAGE: The term applied to one set of nozzles and the succeeding row or rows of moving blades.

UPTAKES (EXHAUST TRUNKS): Large enclosed passages for exhaust gases from boilers to the stacks.

VENT: A valve in a tank or compartment used primarily to permit air to escape.

VENTURI INJECTOR: A device used for washing the firesides of boilers.

VOID: A small empty compartment below decks.

VOLATILE: The term used to describe a liquid that vaporizes quickly.

VOLTAGE TESTER (WIGGINS): A portable instrument that is used to detect electricity.

WATER TUBE BOILER: Boilers in which the water flows through the tubes and is heated by the gases of combustion.

WATER WASHING: A method of cleaning the firesides of boilers to remove soot and carbon.

WELDING LEAD: The conductor through which the electrical current is transmitted from the power source to the electrode holder and welding rod.

WHELPS: Any of the ribs or ridges on the barrel of a capstan or windlass.

WIREWAYS: Passageways, between decks and on the overheads of compartments, that contain electric cables.

WORK REQUEST: Request issued to a naval shipyard, tender, or repair ship for repairs.

ZERK FITTING: A small fitting to which a grease gun can be applied to force lubricating grease into bearings or moving parts of machinery.

ZINC: A metal placed in salt water systems to counteract the effects of electrolysis.

ABSTRACT - This 20-week experimental curriculum bulletin for intermediate and junior high schools was prepared by the New York City Bureau of Curriculum Development. A suggested program schedule outlines topics on Introduction to Flight, Support Systems, and Space and Rockets, including suggested projects, instructional content, and related information for each topic. Detailed information in the form of textual material and directions for making a wind tunnel and other student projects is provided for the Introduction to Flight topic. Additional project directions and information are appended. (SB)

ACKNOWLEDGMENTS

The first draft of the experimental curriculum bulletin, Industrial Arts Aerospace for the Intermediate and Junior High Schools, was prepared as a project of the Bureau of Curriculum Development, Dr. David A. Abramson, Director, in cooperation with the Bureau of Industrial Arts, Herbert Siegel, Director. Dr. Seelig Lester, Deputy Superintendent for Instructional Services, provided overall supervision of the curriculum Development program.

Dr. Daniel A. Salmon, Assistant Director, Bureau of Curriculum Development, served as coordinator of the Curriculum Development Workshop Programs.

The original manuscript was prepared by:

Samuel Garry, Supervisor, Industrial Arts -- Introduction to Flight
Harry Krane, Supervisor, Industrial Arts -- Space and Rockets
Nathan L. Friedman, Supervisor, Industrial Arts -- Support Systems

Acknowledgment is extended to the following individuals for their assistance and cooperation:

Industrial Arts teachers in experimental programs and project development: Howard Kelem, Jerry Berrins, Lance Martin, John Dannecker, Elliot Galland and Kenneth Moynahan.

Commercial Aviation: Jack Shelly, Aviation Development Council; Al Terry and Maurice Wordlaw, Pan American Airways; Eric Talb and James O. Plinton, Trans World Airways; Jeff Milano, American Airlines.

General Aviation: Colonels, Ed Lyons and Jesse Strauss, Civil Air Patrol, Ed West, LaGuardia Flying Service.

Robert L. Cannon, Estes Industries and Bernard Spar, District 27 Queens.

These materials are being distributed to selected intermediate and junior high schools for tryout and evaluation. Suggestions for modification of the final publication are solicited and should be returned by June 1, 1972 to:

Dr. Daniel A. Salmon
Assistant Director
Bureau of Curriculum Development
131 Livingston Street

PREFACE

"After decompressuring the LM, Astronaut Neil A. Armstrong crawled onto the craft's front porch and into the airless vacuum of the moon. He carefully climbed down the lunar lander's steps, placed his right foot into the spaceship's landing pad and at 10:56 P.M. E.D.T., July 20, 1969 stepped from the Lunar Module to become the first earthling to ever set foot on the moon."[1]

This "...one small step for man, one giant leap for mankind"[2] was only the latest of a series of "giant leaps"by men and machines in man's quest of air and space that started some 1000 years ago. The Industrial Arts Junior and Intermediate School Aerospace Program is designed as an introductory course for our students in which they will explore and engage in meaningful activities to help them understand how we arrived at the Space Age on July 20, 1969.

9517

The teachers who have limited experience and background in aerospace and model building should spend some time informing themselves and organizing their shops before embarking on the program. Skim through this publication and then reread sections and one or two books in each bibliography. Build a model or two in privacy and make several assembling or sanding fixtures. Build a wind tunnel and one or two instruments. Write to several sources listed and buy a magazine or two. Start decorating the shop with free industrial and government charts and illustrative materials related to aerospace. Ask your students who build models at home to bring them in and explain their hobby to the class. You may find some real experts in your students or even their parents.

If your school joins the National Aerospace Education Council you will receive five dollars worth of free educational materials. Send for a free film or film strip and review it with a colleague or one of your classes. When you have compiled enough material and prepared lesson plans and instruction sheets try a basic project with your best class or a small group of students who have completed their regular shop work. Alter your initial plans and note any additional preparation (if any) that would have been needed had you been conducting the full program.

Determine what changes will have to be made in your present shop organization for the storage of models, fixtures and special supplies. In your trial project work with the class, note the different tools the student will need. Are there changes needed on the tool board? Can your students handle the special wood, razor and knives and special cements and dope?

Try a few related lessons shop talks and see if your students would be interested in aerospace. They may be able to do the Flight and Rocket Sections but Weather and Navigation might be too advanced. Discuss the scientific and mathematical concepts that the academic

9518

teachers are covering in the school. Are there possibilities for coordinating your work with theirs? Use the information in this publication and contact some of the teachers and supervisors who helped prepare it for additional aids and suggestions. Have your assistant principal and principal evaluate your student's work to determine whether they could provide additional funds for a full term experiment with one class.

Prepare a list of tools and materials that would have to be purchased for one class to begin the program in the Spring term. Show the list and your models to the principal along with a suggested term plan, similar to the one in this manual. You may draw extensively from this publication or you may make up your own. By the beginning of the Spring term you should be ready to try the program with one or two of your best classes. Start with a new set of Safety Rules and a slightly different class organization. Make all your lesson plans and instruction sheets on rexograph stencils and don't be afraid to change them frequently. Give your students opportunities to experiment too as long as they use save and appropriate construction techniques. Keep a daily log of your lessons, students progress and an evaluative sheet on your successes and failures. We will ask you to evaluate this publication before the summer of 1971 to determine its value to you and your students.

GOOD FLYING.

Introduction To Flight

A review of the most familiar vehicle, the airplane, and an introduction to one of the least understood elements, air, can begin our study of aerospace. We hope to arrive at that point in time when the results of many thousands of men's efforts with countless machines produced the foot prints in moon's dust and brought the astronauts safely home. Constructing gliders, airplanes and rockets will help us understand the means of flight. The study of air, weather, navigation and space will be supplemented by the construction of measuring instruments related to flight and space travel.

Following a short introductory demonstration and exhibition by the teacher of models and projects, the students should construct their own paper gliders. The purpose of this activity is to learn basic nomenclature of an airplane and to demonstrate how control surfaces function.

Vocabulary

a. fuselage

b. wings

c. stabilizer

1. rudder

2. elevators

d. center of gravity

e. pitch

f. yaw

g. roll

Procedure:

1. Duplicate sheet of SODA-JETS (Appendix A) on 90 lbs. index.

2. Provide scissors, glue and masking tape to assemble parts on plastic straws.

3. Provide small balsa nose plugs and sandpaper. (Extra masking tape or paper clips may be used to balance the model.

4. Demonstrate assembling parts and identify parts. Adjust for dihedral angle.

5. Demonstrate the method of balancing the aircraft by adding or reducing nose weight.

Discuss and Demonstrate

1. The action of the gliders depend upon weight of fuselage, wings and stabilizers being balanced about the center of gravity. The wings of the glider are to provide the lift or resistance to the air to remain aloft. The stabilizers, vertical and horizontal provide the steadying surfaces to provide straight flight.

Fig. 1

Elevator movements generate forces that cause pitching about the lateral axis.

Fig. 3

The rudder controls yawing movements about the vertical axis.

Fig. 2

Manipulation of the ailerons varies forces so as to effect a rolling movement about the longitudinal axis.

9523

Fig. 4

All movements take place about the axes of the aircraft. These axes all pass through a common point, the center of gravity.

Blacker, Robert D.

Basic Aeronautical Science
And Principles of Flight

Chicago, Ill., 1959

American Technical Society, pg. 119, 120

2. Control Surfaces are provided to permit the glider and an airplane to turn on its three axis.

   Ailerons - Longitudinal Axis - Rolling

   Rudder - Vertical Axis - Yawing

   Elevators - Lateral Axis - Pitching

   See Figures 1 - 4

3. Have students demonstrate their ability to fly the model straight, as well as any of the following maneuvers.

   a. climb

   b. dive

   c. roll

   d. climb-stall-dive

   e. climbing turn

   f. diving turn

   g. loop

   h. spin

Alternate models may be made from Model Aircraft Laboratory CAPP 33, Appendix B or "How to Build A Barnaby Model", Appendix C.

Try to identify as many parts of an airplane from Cessna's "How Well Do You Know Your Airplane?" Appendix D.

THE ATMOSPHERE

Although we have lived in the atmosphere about us, it is difficult to imagine since we cannot see, touch, smell, taste or hear it, except when the air is moving and working. Air may lift kits, paper and airplanes. We may feel its pressure or effects of a vacuum (the absence of air) when we stand in front of a window fan. Heated air warms us. We can hear it as the wind moves it out of the trees and around sharp corners. We can see its strength as it holds up cars or moves heavy lifts above the floor.

The properties of the air that affect flight are:

1. pressure or weight
2. density or humidity
3. movement

Air Pressure:

a. Atmosphere about earth to 4 mi. high

b. Troposphere 4-11 miles

c. Stratosphere 11-50 miles

The air pressure decreases as we go higher into the air. At sea level, it is measured as a barometric reading of 29.92 inches of Mercury or 14.7 lbs. per square inch at 59° F. Each factor of heat, altitude and humidity will affect flight as well as the barometric reading or pressure of the air.

The humidity or density of the air is the measure of the amount of moisture in the air in relation to the amount of moisture the air (at the temperature and altitude) can hold.

The speed and direction at which the air passes the glider or plane will determine the lifting power of the air and the altitude at which the plane may fly. The movement of the air about the plane is affected by many forces:

1. thrust of plane
   a. throwing by hand
   b. rubber band power
   c. small engine - propeller
   d. large engine - propeller
   e. jet
   f. ram jet

2. Lift
   a. size and shape of wing

3. Weight
   a. total weight of airplane

4. Drag
   a. resistance surfaces present to the air.

(See Figure 5)

Figure 5

Indicate on Instrument Panel (Figure 6) the instruments related to air pressure, humidity and movement. On the ground air speeds are measured by an anemometer. This is important for each pilot to know the ground air speed befor he lands or takes off. Students may observe the action of a demonstration anemometer (Appendix E) and selected students may wish to make their own. The anemometer should be calibrated to operate with the wind tunnel demonstration. Students may also wish to build other instruments for a weather station. (See Weather Section). The New York Times Daily Weather Reports and Forecast may be used to calibrate and check shop made instruments. Barometric pressures, wind speeds and direction and temperatures and humidities are recorded each day.

Typical single-engine, light-aircraft instrument panel configuration of the GAT-1 flight trainer.

(Figure 6)

A 30" x 40" Chart of A Piper Cherokee Panel is available from Piper Aircraft Corp., Lock Haven, Pa.

THE WIND TUNNEL

The wind tunnel, more than any other piece of equipment in the Aerospace Shop will enable the student to see, test and control air currents over a "flying" model. The unit (shown above) for this purpose was designed by the Aviation Development Council for their elementary school auditorium programs. It may now be seen at the Aerospace Education Resource Center, 86-50 109 Street, Richmond Hill, N.Y. Mr. Bernard Spar, Science Coordinator will demonstrate it as well as provide an interesting program for scheduled classes. Each teacher should make his own for testing and "flying" student made models. Students may wish to build their own for use at home. The unit is made around an 18" x 18" two speed window fan. The circulating air is straightened before it reaches the model by two sets of venetian blind slats built at right angles to each other.

(See Fig. 7)

Fig. 7

fishing weights
¼" D
rod
WIND
DIRECTION
1/8" D
rod
1/8" D support
rods
STORAGE BOX

Fig. 8

Control arms may be built into the horizontal slats to simulate elevator control on the model.

The model is suspended by pivots approximately 1/3 distance from the lead edge to trailing edge. It sould be balanced at this point prior to attaching it to the counter balance lever. (See Fig. 8) The fishing weights are adjustable to counter balance the weight of the model. This will permit the wind from the fan to provide the pressure differential over the cambered wing to lift the model for a test "flight".

This "tunnel" will only test and demonstrate a model's balance and lift. The construction of a tunnel and a measuring instrument for drag and lift characteristics of an airfoil for advance studies can be made from plans in Appendix F.

BASIC PROJECTS

The choice of the basic project may be among two or three models previously prepared and effectively demonstrated by the teacher.

1. Glider
2. Solid model
3. Rubber powered flying model

The choice may depend upon the age and maturity of the individual students. Each demonstration lesson should be readily adapted to any one of the models. Students should have provided detailed full size plans and/or templates and instructions. Variations for individual differences may be provided within limits of aerodynamic principles as well as finishes. (See Figure 9). Air foils, proportionate sizes and finishes may be altered without appreciably changing the flight capabilities of the craft. Alternate design procedures may be on instruction and information charts for reference by individual students. (See Appendix G).

The use of assembling and gluing fixtures prior to or following the partial finishing of wood surfaces should be demonstrated on the teacher's models. The chances of success of these initial efforts on the part of the student will be significantly improved by well made accurate and easily used fixtures. They should be in sufficient numbers for use by a student as the need arises. Appendix H describes a method for gluing the diehedral angle of a solid wing. Students should be encouraged to make their own fixtures so that they may persue this activity as a hobby at home. (Republic Thunderjet Project diagrams fixtures that can be made). The source of models and plans suitable for a first project can be found in numerous books and magazines. Those in this publication have been successfully used in experimental classrooms over the past year.

BASIC GLIDER

"THERMIC 20" by: Jetco Models,

Brooklyn, New York

MATERIALS: Sheet Balsa

wing, 3/16 x 2 1/2 x 18

pod, 3/16 x 1 x 5 1/2

boom, 3/16 x 3/8 x 12

stabilizer, 1/16 x 2 x 7

fin, 1/16 x 2 x 2

CONSTRUCTION:

1. Transfer with pin wing template to 3/16 balsa blank 2 1/2 x 18. Use the half pattern on each side. (Figure 1)
2. Cut wing shape with knife and sand smooth wing camber. (Figure 2)
3. Apply two or three coats (allow each coat to dry) balsa filler. Sand smooth. (See Appendix I)
4. Cut out pod and boom from 3/16 stock.
5. Glue and pin (use Lance #2 T pin) and allow to dry. (Figure 3) Apply preliminary finishing after rounding the edges and sanding smooth. (Wing and stabilizer surfaces to remain flat.)
6. Transfer patterns for stabilizer, fin and finger rests to 1/16" balsa blank.
7. Sand airfoils on stabilizer and fin. (Figure 4)
8. Fill with balsa filler and sand smooth.
9. Cut wing in half and sand dihedral angle. (Figure 5) Be sure to keep top of the wing up on sanding fixture.
10. Weight one wing on wax paper and cement dihedral angle. (Figure 6) Use weight to hold down both wings until dry.
11. V-slot boom for the wings at the dihedral angle. (Figure 7)

12. Set fuselage into assembling and glueing fixture to hold all parts accurately and secure while the glue is setting. (Figure 8)

13. Glue finger rests under skin. (Figure 9)

BALANCE:

14. Stick pin in Balance Point (Figure 3) and suspend model with string. Balance with wire solder imbedded in the nose. Use clay for fine balance.

FINISH

15. Paint with clear or colored dope. Apply appropriate decals.

LAUNCHING

16. Hand launch. Add or decrease clay until model has smooth glide. (See Appendix J)

INSTRUCTIONS FOR ASSEMBLING

Study the drawing and instructions carefully and thoroughly before starting construction. The quality of workmanship is important on these models. They must conform to the templates if they are to be true models, and although the parts are ready shaped there are some pieces that require sanding to exact shape so that templates will fit perfectly and all parts will conform with the drawing. Scoring of model as explained in Step 8 should be done after parts are sanded but before they are assembled. For some models it can be done after assembly, but on this particular model it should be done before assembly.

CAUTION: Trial assembly of pieces to check fit. alignment, etc. is always a good practice. Then adjustments can be made, if necessary, before pieces are actually glued in place.

Step 1: TEMPLATES

Cut out carefully (with scissors) the fuselage templates B, C, D, E, wing airfoil templates and dihedral gauge. Mount on stiff but light cardboard, using rubber cement, shellac or some adhesive that will not change the size of the template. Cut out, being careful not to cut away any outside lines of the template nor leave any paper visible outside the outline drawing.

Step 2: GLUE

Mix only a small quantity of glue at a time. Be careful to use just the right amount of water, adding a little at a time and mixing until the glue is creamy. No clamps needed.

Step 3: SANDPAPERING

Coarse sandpaper is furnished for sanding pieces down to the exact shape. The piece of garnet paper should be glued to the 1/8" x 1" x 5" piece of wood so it can be used as a file for tapering wings, rudder, elevator, etc. The fine sandpaper is to be used for getting all parts smooth after they are sanded to exact shape.

Step 4: FUSELAGE

Sand front end of pilot cabin (1S2) to shape shown on drawing. Glue to fuselage (1S1).

Sand fuselage so that templates B, C and D fit at points shown on drawing, blending in lines between these points. Use coarse sandpaper, if necessary, to remove surplus stock and then smooth entire fuselage with fine sandpaper.

Step 5: TAIL

The leading and trailing edges of the elevator (1S3) and rudder (1S4) must be sanded to shape (see sectional view) after being assembled to fuselage. Glue pieces in place, being careful to line them up properly. The leading edges should be rounded and the trailing edges gradually tapered to a near point. Blend in surface where fuselage and rudder meet.

Step 6: WING

Glue the two wing pieces (1S5 and 1S6) for bottom wing together. Edges are beveled so that correct dihedral will be obtained if pieces are glued together tightly. For accuracy, check with gauge. blocking up ends as shown on sketch.

When thoroughly dry, sand leading and trailing edges to get the proper airfoil. The leading edge should be rounded and the trailing edge gradually tapered to a near point. Use airfoil template to check shape. Glue in place, lining up carefully and let dry.

Cut out fillet patterns and mount on light but stiff cardboard. Glue to the fuselage and wing, leaving 1/4" between the fillets. Use wood filler provided to form top of fillet. Sand smooth when dry.

Sand top wing (1S8) to shape.

Break apart (1S7) struts from veneer sheet. Sand to shape to conform with template. Assemble struts to bottom wing, gluing into slots.

Glue on top wing and when dry sand struts to streamlined shape.

Step 7: OTHER PARTS

Cabin Struts

Dowels for cabin struts are to be cut to length from long dowel. Sand down to size shown on sketch before cutting to length. Glue in place. Holes in fuselage and wing mark position.

Stabilizer Strut

Sand dowel to size shown on drawing. Cut to length and glue in place.

Exhausts

Make two exhaust pieces from veneer scrap left from strut sheet. Cut to shape shown and glue in place. Round edge slightly.

Tailwheel

Cut from same material as used for exhausts. glue in place and round edges.

Glue propeller hub (1S9) in place.

Step 8: SCORING

On the spotter models it is necessary to score in the outlines representing hinged portion of ailerons, wing flaps, rudder, elevator and also all other surfaces as indicated on the template drawing such as nose turret, pilot cabin, etc.

For locating wing and tail marking, cut out templates and lay on surface, marking the locations with a pin. Score, using pin holes and a straight edge as a guide. A knife blade or glass cutter and hard lead pencil can be used for scoring.

Step 9: FINISHING

Models to be used for training and recognition are to be finished in dull black. Before applying any finish use wood filler to fill nicks or to close up any open joints where parts fit together. Be sure the model is smooth and apply two coats of clear lacquer. After each coat has thoroughly dried go over entire model with fine sandpaper. Apply two coats of dull black lacquer, sanding between coats.

THE PATRIOT

by David Garrett

from: American Aircraft Modeler
December 1969

MATERIALS:

Balsa Sheets

1 pc 1/32 x 3 x 36 wing, stabilizer and fin

1 pc 1/16 x 1/2 x 12 WR, 4 each

1 pc 1/8 x 3 x 13 fuselage, and nose parts

Miscellanous

1 pair 1" diamter wood or plastic wheels

2 each prop shaft washers

1 each plastic or wood propeller

1 each 1/2" long leadout eyelet

1 length rubber, 1/8" flat x 36

1 pc .032 dia. x 36 long spring 1 wire (landing gear and hooks)

CONSTRUCTION:

1. Cut out fuselage and nose pieces from 1/8" balsa sheet. Be sure to follow grain in diagrams.
   a. 2 each NR
   b. 1 each #s 1, 2, and six 6 (see nose assembly drawing)
2. Notch fuselage and NR for landing gear wire with sandpaper or file. File #2 and #6 for eyelet and glue it in place.
3. Bend landing gear wire from 1/32" wire.
4. Assemble nose pieces and glue in numerical order as shown in detail. Sand edges smooth after the glue is dry.
5. Bind and reglue landing gear wire below the fuselage.
6. Cut four WR ribs from the 1/16" balsa.

7. Glue two to the fuselage, one on each side of the wing mount. (give fuselage preliminary sanding and filling.)

8. Cut wings, stabilizer and fin from 1/32" balsa.

9. Cement two WR on each wing panel. (sand and give preliminary filling)

10. Cut and bend rear hook and propeller shaft. Bind and glue rear hook to fuselage. Do not extend binding under the stabilizer.

11. Cut V-slot in fuselage for wing at dihedral angle.

12. Construct dihedral fixture to hold fuselage and wings at designated angle. Apply glue fillets and allow to dry throughly.

13. Construct empannage fixture for assembly and gluing of the stabilizer and fin.

14. Attach wheels

15. Finish with one or more coats of dope or paint. Draw or apply appropriate decorations.

MOTOR AND PROPELLER

16. Purchase or carve and finish the propeller. (See Appendix M)

17. Assemble propeller, washers and prop shaft and bend wire as shown in diagram.

18. Make a 8 1/2" loop of the 1/8" rubber. Knot in the middle. Lubricate rubber for improved performance.

BALANCING:

19. Stick pin into balance point and suspend the model. Add weights (wire solder or lead) as needed.

INITIAL GLIDE TRIM

20. Warp slight up elevator into the stabilizer.

21. Warp appropriate aileron if model turns to left or right. (See Appendix J)

FLIGHTS

22. Initial flights may be made with 100 to 150 turns. Launch slightly nose down after letting prop go for a few turns.

23. Later flights with appropriate warping to adjust flight characteristics at 200 to 250 turns.

9548

WHIP-POWERED U-CONTROL

REPUBLIC F-84 G THUNDERJET

Designed by: Joe Wagner
American Aircraft Modeler
July 1970

CONSTRUCTION:

1. Cut out all parts from full scale drawings. Make wings in one piece. (Figure 1)

2. Sand all parts. Round outer edges. Camber wing and sand airfoil on stablizer elevators and on sanding board (Figure 2)

Sanding boards, to be clamped in vise.
Provide similar boards of appropriate sizes for other parts.
(1) 1 1/4 x 3 x 15
(2) 3/4 x 4 x 15
(3) wing shape

3. Use balsa filler on all wood parts (See Appendix I)

4. Set fuselage in assembly fixture and cement horizontal stabilizer and fin.

Empannage Fixture. Adjust fuselage with tail skid so that the stabilizer will be horizontal with the fixture and perpendicular to the fuselage.

(1) 3/4 x 2 7/8 x 4, 2 each end supports

(2) 3/4 x 1 3/8 x 4 2 each fuselage supports

(3) 3/4 x 4 X / 7 base

The empannage fixture shown above with fin in place. Stick pin in fin. String will hold it perpindicular to stabilizer until glue dries.

5. Cut wing in half. Sand dihedral angle (Figure 4)

Dihedral Angle Sanding Fixture

The sliding sanding board has fine sandpaper glued to one side.

The wing is held steady as the board is moved back and forth.

(1)	3/4 x 4 x 9	base
(2)	3/4 x 4 x 7 1/2	wedge support
(3)	9/16 wedge x 4 x 7	dihedral angle
(4)	3/4 x 5 x 4	sliding sanding board
(5)	3/4 x 3 x 4	support bolock attached to base

6. Lay one half of the wing flat on a gluing board coverd with wax paper. Raise the other wing tip 1 1/8" off the surface. Cement wings at the dihedral angle. Weight both wings until glue is dry. (See Appendix H for alternate glueing method.)

7. Install bellcrank with 1/8" dowel and cement extra balsa scraps on both sides of the fuselage. Make sure the bellcrank is in the correct way and moves freely.

8. Sand wing slots in fuselage to receive wing.

9. Set fuselage in fixture and cement wings in place. Recement dihedral angle and glue fillets under and over wings (Figure 5)

Wing-Fuselage Fixture

Check vertical and horizontal angles before the glue dries.

(1) 3/4 x 3/4 x 4	2 each fuselage supports
(2) 3/4 x 1 3/16 x 4	2 each wing supports
(3) 3/4 x 4 x 15	base

10. Secure fuselage in empannage fixture and sew on elevators. Attach elevator jointer and horn. Elevator must work easily within vertical stablizer.

11. Glue wing tip tanks and small fins to wings. Quick setting glue and pins may hold pieces in place until glue is dry.

12. Hollow out front of fuselage and fill with lead or clay to balance (See Appendix J)

13. Dope or paint model and apply appropriate decal decorations. (See Appendix I)

14. The canopy, rudder, ailerons and flap outlines may be drawn on model with felt pen.

15. Measure, bend and attach .045 dia. music wire rod between bellcrank and horn. Spot solder ends to prevent them from working loose in flight. Test bellcrank to operate elevators.

JET POWER GLIDER

A full size blue print will be made available to teachers.

MATERIALS: BALSA SHEET:

1 pc 1 x 3/16 x 18	fuselage
1 pc 3 x 3/16 x 18	wings
1 pc 2 x 1/16 x 12	empennage

1 power pod

1 Jetex 50 engine

1 launcher

CONSTRUCTION:

1. Make full six size patterns from blue print.
2. Transfer patterns and cut out all parts.
3. Sand and partially finish all parts. See Appendix I
4. Construct empennage fixture suitable for model.
5. Assemble and glue stabilizer, fin and dorsal fin.
6. Cut wing in half and sand dihedral angle in sanding fixture.
7. Glue wings at dihedral angle. See Appendix H.
8. Secure model in second fixture and cement wings to fuselage. Apply cement fillets around joints.
9. Complete finishing and apply decals.
10. Attach Jetex engine to engine pod.
11. Balance model by adding weights until a smooth glide is achieved.
12. Construct launching devise.
13. Follow manufacturers directions for installation and ignition of the jet engine.
14. Review safety procedures with students regarding:
    a. installation of jet pellet
    b. placement of igniter
    c. lighting the igniter

d. clearing the area of lift off

e. procedure for misfire

f. following and recovery of the model.

STUDENT DESIGNS:

The relative simple design of this glider with a constant power element of the jet engine lends itself to student redesign and a study in research and development. The teacher should demonstrate and encourage redesign possibilities in any of the following areas:

a. variation in size and shape of the wings

b. changes in the empennage in size as well as position

c. increase and decrease in the dihedral angle

d. polyhedral, tip dihedral

See Appendix G

Testing, recording and evaluation of the flight characteristics may be evaluated in group and class sessions.

ENGINE
GLOW-PLUG/U-CONTROL KIT

1. Past experience indicates that the initial U-Control engine model might best be constructed from a commercial kit. The variables in this new venture would be measurably decreased for the student and the teacher. There are still sufficient educational experiences and adjustments that will be required of the novis student and the teacher who has had limited experiences in model making and flying.

2. Purchasing may be done via small value funds from a neighborhood Hobby Shop. At quantity purchases, some shops will give up to 40% school discount on kits, engines and accessories. The two models with which we have had the most success are the Sterling: Beginners Ringmaster, Kit #S 30, Wing Span 8" x 21", Engine .049 displacement and the Sterling Curtiss P-40 Tiger Shark, Kit #S-7, Wing Span 27 1/2", Engine .09 to .19 displacement. (See Figures #1 and #2) Both are profile fuselages. The Tiger Shark is built with a rib wing. Other suitable models are shown in Figure 3.

3. Construction of the models should follow instructions provided by the manufacturer with the kit. The construction of assembling and glueing fixtures by the teacher and or students will improve the appearance of the model as well as its flight characteristics. Fuel proof cements should be used on all parts. The fixtures will allow the parts ~~to~~ dry throughly while being held stationary. A special storage arrangement should be devised so that work can be held over from day to day. The teacher should provide extra balsa wood and fittings in the event parts are missing or broken during the construction operations. There are numerous opportunities for group or class lessons on finishing, soldering and wire bending as well as reading and following plans. The teacher may supply supplimentary

instruction sheets to those children who are able to follow diagrams and instructions by themselves. Figure 4 shows a diagram that may be included in covering the wing of the Tiger Shark.

4. The purchasing of the engine, gas tank, propellers, fuel, fuel lines batteries, battery clip, control handle and control lines might be made on an individual, group or class basis. Engines list in price from $5.47 for a .049 displacement and up. We have had some successes with the engines with built in spring starters. The automatic battery operated starters list for $24.95 without the battery. The Miniature Internal Combustion Engine Information Sheet (following) should be included in the instructional phase of the model building. Students may have their own or use the group or class engine. One advantage of fewer engines and control lines is that the organizational control by the teacher is simplified if he has to watch fewer flying models at one time.

5. The finishing of the models and the application of appropriate decals (See Figure 5) will do much to enhance its appearance.

6. Testing and flying in the school yard should be conducted with all necessary safety precautions and as many school aids as possible. Chalk the flying circle and spectator area. If students have test run their engines in the shop, there should be little difficulty in running the engine in the yard. Provide a table or have students field caddies on which to work. Assist the students in their initial flights since U-Control is not as simple as it appears, especially the first few times around.

7. Special note to the teacher: PRACTICE

Figure 5

MINIATURE INTERNAL-COMBUSTION ENGINE

1. Read the operating instructions of the manufacturer carefully.
2. Attach the proper size propeller.
3. Construct wooden break-in fixture and run the engine at least six different times, or six tank fulls before installing it in the model.

LESSON-DEMONSTRATIONS:

a. Construction and parts of a glow plug engine. Figure 1

b. Engine specifications

c. Demonstrate the operation of a four cycle automobile engine Figure 2.

d. Comparison and operation of the two cycle engine. Figure 3

e. Operation Procedures:

(Follow recommendations of the manufacturer)

1. Install engine in model with lock washers or airplane nuts.
2. Install tank and appropriate platic fuel lines.
3. Attach proper size propeller.
4. Observe special safety precautions when filling the fuel tank with manual or automatic pump.
5. Adjust needle valve and prim the engine.
6. Attach starting battery with glow plug clip.
7. Turn over engine. Trouble shoot if it is difficult to start.
8. Observe safety procedures when the engine starts:
   a. keep hands from propeller
   b. be sure back fire has not loosened the prop.
   c. adjust needle valve
   d. remove battery clip
   e. be sure ventilation is adequate if operation is indoors.
9. Adjust engine to run at maximum rpm.

MODEL AIRCRAFT

CAPP 33

LABORATORY

PUBLISHED BY NATIONAL HEADQUARTERS
CIVIL AIR PATROL
MAXWELL AFB, ALABAMA 36112
Reprinted by the
FEDERAL AVIATION ADMINISTRATION

GA-20-71

MODEL AIRCRAFT LABORATORY

1. Purpose. The Model Aircraft Laboratory provides a controlled laboratory situation in which each individual participating in the CAP aerospace education program can demonstrate his knowledge of (1) the scientific principles of flight, (2) the characteristics of aircraft in flight, (3) the in-flight effects of primary control surfaces, and (4) the movements of an aircraft about its three axes. The Aerospace Education Officer is responsible for conducting the laboratory, and he must certify that each participant has successfully completed all of the requirements listed in paragraph 3 of this pamphlet. Satisfactory participation in the laboratory is a requirement for completion of the Wright Brothers Achievement in Phase II of the Civil Air Patrol Cadet Program. When the laboratory is completed by a CAP cadet, the Achievement Record on the individual's CAP Form 66, "CAP Cadet Master Record," will be properly annotated, and the completed checklist in this phamphlet placed in the cadet's master record.

2. How To Conduct the Laboratory:

a. Physical Layout:

(1) Obtain the use of a large area (room, gymnasium, ramp, etc.) sufficient to allow the flight and observation of paper and balsa gliders.

(2) On the floor of the laboratory area, construct (with chalk, tape, or string) a straight line 15 feet long with a 6-foot crossarm at one end, as shown in figure 1.

(3) Provide a table or other suitable flat working surface for use by personnel conducting and participating in the laboratory. The table should be located as shown in figure 1.

b. Aircraft. Each participant will bring two model aircraft to the laboratory.

(1) Aircraft "A" will be a paper aircraft constructed as shown in figure 2.

(2) Aircraft "B" will be an assembled, hand-launched balsa glider.

(3) Each participant will print his name on each side of the fuselage of each aircraft for identification purposes.

Figure 1.--Floor plan for Model Aircraft Laboratory flight area.

Figure 2.--Directions for constructing paper model Aircraft "A."

c. Procedures:

(1) Each participant will report to the laboratory flight area in the order directed by the Aerospace Education Officer.

(2) Each participant in the laboratory may not observe the exercise until his own performance has been evaluated.

(3) Each participant will report to the laboratory with the two aircraft described in paragraph 2b, assembled and ready to fly.

(4) When called, each participant will approach the laboratory flight area with both aircraft in his left hand. Each Civil Air Patrol cadet will report in a military manner to the assisting cadet officer as follows: "Cadet ___(grade)___ ___(last name)___ , ___(first name)___ , ready to fly, Sir."

(5) The Aerospace Education Officer or his assistant will announce each demonstration to be performed, all of which are contained in the Individual Checklist for the Model Aircraft Laboratory shown in paragraph 3. The participant will then demonstrate his knowledge, understanding, and/or abilities in each category of participation.

(6) The Aerospace Education Officer will observe each participant's performance and record on an individual checklist a "P" (for pass) or an "F" (for failure) in each step. The participant may progress from one checklist item to the next without achieving success; however, each item must be performed successfully before credit for satisfactory completion of the laboratory can be given.

(7) At the end of the checklist, the participant will be graded by the Aerospace Education Officer as a success or failure in the laboratory. If performance of any of the checklist items has been unsatisfactory, the areas of failure will be identified. An opportunity will be provided, outside the regular meeting schedule, for each individual with unsatisfactory ratings to satisfactorily complete the exercise. Once any item on the checklist is successfully completed, that item does not have to be reaccomplished.

(8) Upon completion of the laboratory period, which will take place during the first 50-minute instructional period of Meeting 6 in the Wright Brothers Achievement, the Aerospace Education Officer will report to the commander of the squadron the results of the laboratory and advise him of the time and place scheduled for a re-examination of individuals with unsatisfactory ratings.

3. Checklist To Be Completed. The Aerospace Education Officer, or his designee, will assure completion of the following checklist for each individual participating in the Model Aircraft Laboratory as follows: (1) Announce each checklist item in numbered order, (2) observe and evaluate the participant's performance on that item, and (3) enter an "X" in the appropriate block to denote pass (P) or failure (F).

INDIVIDUAL CHECKLIST FOR MODEL AIRCRAFT LABORATORY

How To Build A Barnaby Model

Here's how to make a Barnaby model. Take a sheet of 8½-by-11-inch bond paper and fold it in half widthwise (Fig. 4–1*a*). Open it and lay it crease down on a hard flat surface. This crease will be the model's centerline.

Fold over a ¼-inch strip along one of the 11-inch edges. Do this in one operation, using the fingers of both hands. The fold must lie flat. Continue folding until at least one-half of the sheet has been folded up (*b*). Remember, each fold must be carefully flattened in a separate operation. Otherwise, you may build a twist into the leading edge. Later, when you try to adjust the model, the wings will not align.

Now bring the two rolled-up tips together and press again along the centerline. Hold the paper in this position and carefully cut or tear along the dotted line, as indicated in Fig. 4–1c. Spread the model out flat and turn up a quarter inch of each wingtip to make wing fins. These fins should be parallel to the centerline and perpendicular to the wings (*d*).

Next, fold *down* the outer portions of the tail surfaces to make rudders, following the angle made by the dashed lines in Fig. 4–1*e*. Note that these folds are not parallel to the centerline but toe in slightly toward the nose.

With thumb and index finger, bend up a small portion of the rolled-up leading edge at the centerline (*f*). This raised portion will act as a truss to stiffen the wings laterally and hold them at the proper angle.

Now camber the wings by scratching along their trailing edge (*g*), as you learned earlier. Hold the model by the tail, between the thumb and first two fingers with the index finger on top and check for symmetry (*h*). If necessary, add more camber to one wing or smooth one out until the two are identical.

Also, check for wingtip symmetry by viewing the model from the side. If the

Fig. 4–1

9577

i

j

k

l

Fig. 4–1

Fig. 4–2

leading edge has been folded right, the creases of the wingtip fins will appear parallel to the centerline (*i*). If the leading edge has not been folded right, these fins may be twisted down (*j*), or one may be twisted down and the other up (*k*). It's practically impossible to get rid of such a fault once it has been folded into the model. It's easier to start over again with a fresh sheet of paper.

Finally, give the model a little up-elevator by pinching a bit of the center fold at the tail (*l*).

You are now ready for launch. Hold the model as shown in Fig. 4–2 and push it gently away from you on a slightly downward path. If you have correctly executed each step in construction, your model should glide along nicely. If not, adjustments must be made.

How to Make Adjustments

If the model dives into the ground, give it a little more up-elevator by cambering the trailing edge of the tail upward.

If the model follows an undulating path, it has too much up-elevator. Try flattening down the trailing edge of the tail. If this doesn't work, chances are your Barnaby is tail-heavy because you did not roll up enough paper in the leading edge. This can be corrected by adding a paper clip to the nose.

If the model glides all right but tends to

yaw, check again for symmetry. Make sure both wings have the same amount of camber. And make sure, too, that both rudders have the same amount of toe-in. If the airplane still tends to yaw, increase the camber on the side to which it turns. Then bend the trailing edge of the rudders toward the other side. Remember to keep your corrections small.

Perhaps you are wondering why I told you to toe in the rudders instead of making them parallel to the centerline. The aerodynamic explanation is quite complex, but the simple fact of the matter is the model flies better that way.

You may have noticed that most professional weather vanes are made with split surfaces at the rear (Fig. 4–3). It has been found that they make the arrow point more steadily into the wind with less wavering of the vane from side to side. The same is true of the toed-in rudders. They keep the glider on course and they keep it steady.

There is another way to loop the loop. Hold the model nose-up with the top surface away from you. Now pull the airplane straight up, releasing the model in front of your face. The airplane should loop away from you, then return so you can catch it in your hand.

HOW WELL DO YOU KNOW YOUR AIRPLANE

APPENDIX D

Here's another quiz to test your knowledge of airplanes. On this page is an "exploded" view of a Cessna Model 180. You will note that parts are numbered 1 through 21. In the column to the right of the page, fill in the name of the parts, then check your answers (listed upside down in the lower right-hand corner).

NO FAIR PEEKING! A score of 18-21 is excellent, 15-17 good, 12-14 fair; below 12—looks like you'd better do some brushing up.

Developed by: Mr. E. Galland and Mr. K. Moynahan at the Carr Junior High School

ELECTRONIC ANEMOMETER

AIM:

The accurate measurement of the speed of the wind is of considerable importance in aerospace technology. The wind speed will determine the amount of power required by an airplane in take-offs and landings. The wind speed and its direction at the altitudes of the flight of the aircraft will determine the amount of the ground speed over the length of the flight. This in turn will determine the amount of fuel the plane must carry. Each airport must have an anemometer to measure the wind speed so that the information may be relayed to each pilot leaving and arriving.

INTRODUCTION

The construction of a simple electronic anemometer can be an introduction to the entire field of electronic and mechanical instrumentation. The students may also use this instrument as one of a series for a weather station. Others may include a wind direction indicator, rain and snow gages, barometers, thermometers and sling psychrometer. The model shown may be duplicated or adapted by the student and teachers for their particular use. The instrument may be mounted outside a window and the meter installed in a room.

CONSTRUCTION: METAL SHOP

1. Design and construct the metal container and motor support.

   a. shop sketches
   b. sheet metal layout
   c. transfer design to metal
   d. cutting and forming metals
   e. joining metals
   f. drilling holes for wiring and mounting of meter

2. Design and construct wind cups and holders

   a. forming copper - dieblocks and dapping punch
   b. soldering
   c. drilling motor shaft mount (set screw or key shafts)

3. Finishing

   a. painting on metals

CONSTRUCTION: ELECTRIC SHOP

4. Design electronic circuit

   a. principle of the generator
   b. principle of meters (microammeter)
   c. principle of capacitors
   d. soldering of electrical connections

5. Mount motor and meter, wire capacitor and test unit.

6. Optional electronic construction: Use a 3 way switch for a variation of scale readings on the meter.

CALIBRATION:

1. Calibrate the anemometer with a commercial instrument.
2. Choose a relatively calm day. Extend the instrument out of a car window and calibrate with speedometer.
3. Substitute meter's scal for one of miles per hours or attach a conversion table to the side of the anemometer.

9584

A RETURN TYPE WIND TUNNEL

DESIGNED BY
H. ALLAN LACEY
GARDEN CITY HIGH SCHOOL
GARDEN CITY LONG ISLAND

The construction of a wind tunnel is an ideal industrial arts group project. The model illustrated was designed for use in aviation classes. It is an interesting and practical piece of equipment for the school shop and will stimulate the experimental work in aerodynamics outlined in this course.

Only basic dimensions for the tunnel are given. Slight changes can be made without destroying its effectiveness. Substitute materials can be used.

The lift and drag instrument is rugged in construction, yet sensitive in operation. Although the original model contains aluminum castings for the main and pivot frames, built-up frames would be equally satisfactory. Lift and drag arms also are of aluminum. However, any metal can be used. Wood could be used for these parts if suitable bearings were installed for the pivot screws. The instrument is mounted on a suitable heavy base such as a large brake drum. Because the unit is separate from the tunnel, it is easily accessible and can be moved when not in use.

The fan is driven by a half-horsepower motor. The fan shaft is connected to the motor shaft by a simple flexible coupling. The air speed is approximately 35 m.p.h.

Wooden test models of various airfoil cross-sections are five inches square. They are equipped with 1/8" pins for mounting on the end of the lift arm. Typical airfoil shapes are shown on pages 74 and 75. Other types of models can be used. The testing procedure is given on page 70.

RETURN TYPE WIND TUNNEL - DETAILS

RETURN TYPE WIND TUNNEL - DETAILS

Additional equipment such as a wind speed indicator and various smoke testing devices utilizing dry ice will be valuable. Likewise, a small protractor mounted at the end of the lift arm will aid in setting the airfoil model at the desired angle of attack.

LIFT AND DRAG TESTING INSTRUMENT

1 BASE PLATE
2 GUIDE PLATE

4 PIVOT FRAME
5 LIFT ARM
6 DRAG ARM
7 WEIGHTS
8 AIRFOIL MODEL
9 PIVOT SCREW
10 STOVE BOLT
11 CONDUIT PIPE
12 PIPE NUT

TESTING PROCEDURE

1. MOUNT AIRFOIL MODEL ON LIFT ARM. USE A PROTRACTOR HEAD WITH LEVEL TO SET AIRFOIL AT DESIRED ANGLE OF ATTACK. CENTER AIRFOIL BETWEEN TUNNEL OPENINGS.
2. COUNTERBALANCE AIRFOIL ON LIFT ARM BY ADJUSTING WEIGHTS. BALANCE DRAG ARM.
3. START MOTOR. BALANCE LIFT AND DRAG ARMS WHILE AIRFOIL IS SUBJECTED TO AIR STREAM.
4. SHUT OFF MOTOR. USE A GRAM OR OUNCE SPRING SCALE TO MEASURE LIFT. SEE LEFT HAND FIGURE BELOW. RECORD MEASUREMENT.
5. BALANCE LIFT ARM BEFORE MEASURING DRAG.
6. USE SPRING SCALE TO MEASURE DRAG. SEE RIGHT HAND FIGURE BELOW. RECORD MEASUREMENT.
7. CHANGE ANGLE OF ATTACK AND RETEST AIRFOIL.
8. COMPARE READINGS OF DIFFERENT AIRFOILS AT THE SAME ANGLE OF ATTACK.

NOTE: LIFT AND DRAG ARMS SHOULD FLOAT IN CENTER OF GUIDE PLATE HOLES WHEN BALANCED.

APPENDIX H

PROCEDURE for OBTAINING DIHEDRAL ANGLE

1. Do not cut the wing completely in two. This makes it short and weak. The wing templates for the most part are already shorter than the wing span dimensions listed on the assembly sheet.

2. Cut the wing part way through with a dovetail saw or similar thin saw blade until it gives. Check dihedral angle. If more clearance is needed, bend and re-saw.

Cut until wing gives.

When saw cut does not give full dihedral angle--

Bend and re-saw.

This method assures perfect alignment of each side.

3. Apply glue, set im simple jig to give proper dihedral and weight sufficiently.

Note:--Place wax paper above and below the glue joint to keep the wing from sticking to the weight or base.

4. Press a few paper staples over the joint for added strength.

SANDING AND SEALING BALSA

Paints, lacquers and/or varnishes cannot replace sandpaper. If balsa surface is not sanded and sealed carefully, it is almost impossible to get a smooth paint finish. Start sanding the finished balsa with a fine sandpaper of 3/0 garnet. Give wood finished sanding with 5/0 garnet. (Fig. 1) Apply one coat of balsa sealer and allow to dry thoroughly, over night preferably. (Fig. 2) Sand with 5/0 or 320 grit or finer sandpaper until surface is smooth again. Apply more sealer and repeat drying and sanding until all pores are filled. (Fig. 3 and 4.)

BASE COAT PAINT

Once you feel the balsa surfaces are properly prepared you may give the wood its base coat of paint. This should be the lightest color to be used on the model. Apply light even coat of the base color (Fig. 5) and set model aside to dry on racks (Fig. 6). Always spray or brush thin coats. Sand with very fine or wet sandpaper and clean surface with rag before applying additional coats.

Second and third colors may then be painted over base color. Use masking tape to make even lines and protect edges. Final touches should be made with commercial decals.

BALANCING FOR FLIGHT

It is important to have your model properly balanced or it will not fly. Balance model on your finger, holding it ⅓ of the distance from the front edge of the wing to the rear edge. Add weight (clay, chewing gum, etc.) in the nose until the proper balance is attained. Make sure wings and tail surfaces are not warped.

Hold plane at eye level and throw straight out.

If plane dives too sharply, bend elevators up.

If plane climbs too sharply, bend elevators down.

When properly balanced, plane should glide for about 50 feet.

dive--nose heavy

stall--tail heavy

flat glide--properly bal[illegible]

THE PROPELLER

IN A MODEL PLANE, the propeller is a most important part. There are all types of propellers each designed for a special job, and in its finished form the propeller provides pulling or pushing power, speed or climb.

For the type of models shown throughout this booklet, the most efficient prop here illustrated is known as the STANDARD type. It is one of the easiest to carve.

A study of the various stages of carving a prop will convince you that without further hesitation, you can select your propeller block as specified by the plans of the model you've just built, use your X-ACTO knife and go to work.

The beginner builder would do well to follow the propeller design given when building a model from plans. It is assumed that the designer of the model has tested his craft thoroughly to get the best results with the propeller in question. Indoor models as a general rule are flown with propellers whose dimensions are about ½ the span of the wing. On outdoor models (excluding gas jobs) propeller sizes are about 1/3 the span and are designed for higher speed.

Carving the Prop

THE BLOCK of wood chosen for the prop is called a "blank". A properly dimensioned blank may be purchased at any model shop. First step is to draw diagonal lines across the face and back of the block. The "X" blank is then cut to shape with your X-ACTO knife or Hobbycraft Saw. Be sure the hub section is left fairly thick. The sketches illustrating the carving steps are simple to follow. Work easily and carefully across the face of the blade from hub outward in a gentle scooping out or concave motion. Do not attempt deep

cuts and do not cut close to the outer edges. When one blade is semi-carved, work on the other blade in similar fashion.

Next turn the prop over and carve the CONVEX shape in the blades. Working out from the hub where it is thickest, remove the top surfaces in easy cuts until the blade has a tapered thickness at the edges of at least 1/8 of an inch. For the time being the hub should be the thickest part since strength is needed in the center portion because pressure is applied by the weight of carver's hand.

Sanding and Drilling

The next step is sanding the blades down smoothly. Using your fingers under the right hand blade (opposite if a "lefty") as a means of support, rub medium grade sandpaper over the surface to remove the rough spots. Finish with fine sandpapering. Round off the ends of the blades as shown in the sketches.

Now mark the center of the prop, drill a hole the same size of the wire prop shaft to be used and then balance horizontally. The heaviest side of the blade will naturally drop down. Sand lightly over the surface and balance again until the prop remains perfectly still in a horizontal position. (See sketch of prop balancer).

Cutting away a part of the hub at the rear of the prop in a scalloping effect, as illustrated in Step 7 makes for lightness and efficiency. Insert the prop shaft, bend the front end to shape and push firmly back into the face of the hub. Apply lots of cement over the joinings. Next, slip a few washers on the shaft before bending the rear end of the shaft into a hook. It is a good idea to cement one washer flush to the rear of the hub.

MINIATURE JETEX
JET PROPULSION ENGINES

Model Power for Aircraft, Helicopters, Racing Cars, Speed Boats.

SCORPION 600 $4.00. For control models. Engine thrust 4 ozs. Duration 7-9 secs. Wgt. 1-9/16 ozs. Lgt. 2¼". Dia. 1¼".

PAY-LOADER 150 $2.00. Engine thrust 1¾-2 ozs. Duration 7 secs. Wgt. 15/16 oz. Lgt. 3-1/16". Dia. ⅞".

ROCKET JET 50 $1.50. For space ships and missiles. Engine thrust 4 ozs. Duration 4-5 secs. Wgt. ⅞ oz. Lgt. 1⅜". Dia. ⅞".

50 HELL-CAT $1.00. Engine thrust ¾ - ⅞ oz. Duration 14 secs. Wgt. 5/16 oz. Lgt. 1⅜". Dia. ⅞".

ENGINE AUGMENTER TUBES to increase engine thrust:
No. 50 @ 70¢
No. 150-600 @ $1.50.

JETEX FUEL PELLETS
50-10 @ 60¢, 50-20 @ $1.00, 50-20 HT @ $1.50, 150-10 @ $1.00, 150-20 @ $1.50. 600-10 @ $2.00

JETEX ENGINES BOOK $1.00

APPENDIX R

TEACHER DISPLAY AND DEMONSTRATION APPARATUS

1. Wind Tunnel - Teacher Made
2. Air-cooled airplane engine from New York State Government Surplus Depot on special engine mount.
3. Airplane propeller from Government Surplus.
4. Control surface simulators - Teacher Made
   See photograph (Circa 1945)
5. Commercial Airline passenger plane models from Public Relations Department of the Airlines.

EXPERIMENTAL EXPERIENCES FOR TEACHER AND OR STUDENTS

1. Design wood molds and draw vacuum formed plastic canopies and cowls.
2. Make plastic injection molds of airplane wheels.
3. Make plaster of Paris molds of fuselage and lay up fiberglass. These may be used with styrofoam wings.
4. Cover teacher model truss fuselage and ribbed wings with transparent monokote to show construction.
5. Construction of Rocket Gantry.

APPENDIX S

CESSNA 150 SPECIFICATIONS

Gross Weight	1600 lbs.
Empty Weight	1010 lbs.
Useful Load	590 lbs.
Maximum Baggage	120 lbs.
Engine	Continental 0-200-A 10
Horsepower	100 HP @ 2750 RPM
Fuel Capacity	26 gallons
Useable Fuel	22.5 gallons
Fuel Grade	80/87 octane (min.)
Oil Capacity	6 quarts

Speeds	
Top speed–sea level	122 MPH
Cruise–75% power–7000 ft.	117 MPH
Take-off speed–normal	60 MPH
Approach speed–normal	65 MPH
Best Rate of Climb–sea level	70 MPH
Best Angle of Climb	60 MPH
Short Field Approach Speed	55 MPH

Stall speeds at Gross Weight	
Clean	48 MPH indicated
Flaps 20°	40 MPH indicated
Flaps 40°	39 MPH indicated

Range	
Cruise–75% power–7000 ft.	475 miles
Optimum range–10,000 ft.	565 miles

Performance	
Maximum rate of climb S.L.	670 FPM
Take-off ground run	735 ft.
Total Dist. over 50' obstacle	1385 ft.
Landing Roll	445 ft.
Total Dist. over 50' obstacle	1075 ft.
Service Ceiling	12,650 ft.

Fuel Consumption	65%	75%
2500 feet	4.8 gph	5.8 gph
5000 feet	4.8	5.6
7500 feet	4.8	5.5
10000 feet	4.8	–

Power Settings	50%	65%	75%
S.L.	2225	2375	2425
2500	2275	2450	2525
5000	2300	2500	2650
7500	2400	2600	2700
10000	2450	2675	–

Airspeed Limitations	
Maximum–Smooth Air	162 MPH
Caution Range	120-162 MPH
Normal Range	56-120 MPH
Flap Operating Range	49-100 MPH
Maneuvering Speed	109 MPH

APPENDIX T

AMITYVILLE FLYING SERVICE

ZAHN'S AIRPORT, AMITYVILLE, N.Y.

CESSNA 150 CHECK LIST

I. PREFLIGHT INSPECTION

1. Master switch on, check fuel quantity indicators, then turn master switch off.
2. Check ignition switch off
3. Check fuel valve handle on
4. Check oil level – 6 quarts
5. Check propeller and spinner for nicks and security
6. Check fuel tank vent opening for stoppage
7. Load within limits
8. No smoking
9. Seats and seat belts – adjust and lock
10. Brakes – test and set
11. Controls free
12. Cabin door locked
13. Radios off
14. Navigation and landing lights off
15. Altimeter and clock set

II. STARTING ENGINE

1. Carburetor heat control in full cold position
2. Mixture full rich
3. In cold weather up to six strokes of priming pump, warm temperatures with one or two strokes of the primer
4. Master switch and magneto switch on both
5. Throttle ¼ inch open
6. Propeller area clear
7. Pull starter handle
8. Check oil pressure, pressure indicated 30 seconds summer, one minute very cold weather
9. Release parking brake and check brakes

III. ENGINE WARM UP

1. 800 RPM – 2 minutes warm weather
   800 RPM – 4 minutes cold weather (below 70°F)
2. Since the engine is closely cowled for efficient inflight cooling, precautions should be taken to avoid overheating on the ground

IV. ENGINE RUN-UP

1. Parking brake set
2. Engine at 1700 RPM
3. Oil pressure 30 PSI to 60 PSI
4. Oil temperature min. 100°F
5. Generator checked for positive charge
6. Check magneto max. drop 75 RPM
7. Check carburetor heat drop
8. Idle engine, check magneto switch both off and then on
9. Radio check

V. BEFORE TAKE OFF

1. Controls free, unlocked, properly rigged
2. Oil temperature and pressure normal
3. Carburetor heat rechecked off
4. Altimeter set
5. Directional gyro set (check suction) 3.75 to 4.25" Hg.
6. Horizon checked for rigidity and set
7. Turn and bank checked
8. Gas on both
9. Mixture rich
10. Wing flaps checked (both) and set for take-off position
11. Trim tab set for take-off (neutral)
12. Engine checked for proper functioning and power
13. Safety belts fastened
14. Cabin door locked – no smoking
15. Accelerate to 50 to 60 MPH before take-off

VI. NORMAL CLIMB

1. Air speed – 75 MPH
2. Full power
3. Mixture rich unless engine is rough

VII. NORMAL CRUISE

1. Cruise 2430 RPM 65% rated power, 111 MPH, 4.8 GPH fuel consumption
2. Lean mixture as required
3. Use power chart when appropriate

VIII. BEFORE LANDING

1. Mixture rich
2. Carburetor heat on
3. Wing flaps as desired below 100 MPH
4. Airspeed 60 to 70 MPH flaps extended
5. Seat Belts fastened

IX. AFTER LANDING

1. Wing flaps up
2. Carburetor heat cold
3. Trim tab neutral

X. PARKING

1. Radios off
2. Navigation lights off if applicable
3. Mixture idle cut off
4. All switches off
5. Parking brake set (use chocks if available)

POWER PLANT EMERGENCY

1. Push mixture control to full rich
2. Apply carburetor heat
3. Check ignition switch
4. Check fuel valve
5. On damp days especially cloudy, foggy or hazy days, regardless of temperature, keep a sharp look-out for loss of power. If the engine begins to lose power, apply full heat and open the throttle. Fuel vaporization can be helped by using hot air when the outside temperatures are between 21° and 50°F. If ice is suspected from a drop in RPM and the air heater is turned on hot to melt the ice a slight additional drop will result. This is normal and if there is ice in the carburetor this slight drop in RPM will be regained as the ice melts.

4. Powered Flight

   a. Wright Brothers - Kitty Hawk

   b. Louis Bleriot - English Channel

   c. C. P. Rodgers - New York to California

5. World War I

   a. French Spad

   b. English - Sopwith Camel

   c. United States - Jenny

6. Charles A. Lindberg

   a. Solo from New York to Paris

7. Beginning of Commercial Aviation

   a. James H. Doolittle - instrument flight

   b. Early Commercial Service

    c. Clarence Powell, TWA First Officer

CAREERS IN AVIATION

First Officer, International Pilot, Clarence Powell

First Officer, International Pilot Clarence Powell has been with the Trans World Airlines since 1966. He is married and has just past his thirty-first birthday. He flew helicopters as a Chief Warrent Officer with the United States Army. He advanced to an Instructor Pilot before leaving the service for a commercial aviation career.

In order to qualify as a First Officer, Mr. Powell had to meet a rigorous training program and a satisfactory employment record as a Flight Engineer on TWA's jet fleet. His qualifications included two years of college at the University of Kansas and Troy State College of Alabama, a FAA commercial instructors rating, 500 hours of flight time and a first class FAA Medical Certificate.

After five years flying as a First Officer, International Pilot, he will be eligible to bid for the next vacancy as Captain.

SPECIAL SUPPLIES AND MATERIALS

1. Balsa wood is available from G-1 list. Special hard balsa would have to be bought from neighborhood or city hobby supply shops (see sources of supplies, below).
2. Laminated balsa may be made by glueing either plastic or brown paper between layers of wood.
3. Reenforce sheet balsa on landing farrings and wing struts by glueing on silk or nylon cloth.
4. Thin plywood - 1/8, 3 ply, is used for fire walls and bulkheads.
5. Bamboo wood can be used for extra strength for struts.
6. Lemon wood may be used for motor mounts.
7. Airplane model fuel-proof cements are required on all models that will have an engine. Rubber power gliders, whip u-control and solid models may be assembled adequately with "Titebond," a strong ready to use adhesive made by Franklin Glue Company.
8. Muscilage is handy for adhering paper covering.
9. Crinoline may be used to strengthen wing and stabilizer joints.
10. Japanese Tissues - available in assorted colors for covering truss fuselage and rib wings.
11. Sheet Plastic or celluloid are used for windows and canopys.
12. Monokote is a new gummed plastic, available in clear or opaque colors. It is used to cover engine - flying models. Can be applied easily with a hot iron. It is also fuel proof.
13. Dope is a special fuel proof lacquer that may be used with gliders as well as flying models. Special ventilation precautions should be taken. Be careful to use thinner recommended since there are different types and they are not interchangeable.

14. Balsa filler may be purchased or made by adding talcum powder or corn starch to clear-thinned dope.

15. Sandpaper is extremely important in preparing surfaces as well as finishes. Use garnet or aluminum oxide papers. Wet papers are used for high gloss finishes. Finger nail emery boards come in handy in tight spaces.

16. Use good paint brushes and keep them clean with appropriate thinning solutions.

17. Flight rubber for power should be lightly sprinkled with talcum powder and kept in a tightly covered tin can. Once installed in the plane, lubricate the rubber with glycerin, liquid soap or a commercial rubber lubricant for improved operation.

18. Assorted hardware:

    fish line and sinkers

    swivels

    glass beads

    cardboard

    very small screws and nuts

19. Metals: piano wire is used for push rods, hooks and skids. Copper wire is used to wrap joints that are to be soldered.

20. Lance #2 T pins are the best type of straight pin for all model work.

21. Single edge razor blades may be purchased from printing supply house.

FIELD DAY

One or two effective field days per term with appropriate preparation, field organization and evaluation should be incorporated in each Aerospace Program. The application and measurement of students' craftsmanship and information will be put to as realistic a test as possible in a competitive spirit.

PREPARATIONS BY THE TEACHER:

1. The student's work, one class or selected individuals from several classes, should be evaluated sufficiently in advance so that the date of the trip will coincide within a week of the finishing of the models.

2. Arrangements must be made for bus, parents and para-professional aides as well as students' parental consent slips in accordance with school policy.

3. The teacher should make one or more trips to the prepared area to determine:

   a. permission to use public park or private area

   b. toilet and water facilities for the number of students

   c. sufficiently remote location from traffic, housing and pedestrians so that flights may be made

   d. appropriateness of the grounds for the activities and events

   e. availability of special apparatus and grounds

      1) U-Control surfaces

      2) wire attachments for CO 2 Rockets

   f. safety of students and adults

4. Each of the activities and events at the field day should be thoroughly planned with groups of students.

a. activity or contest

b. participants

c. schedule of activities

1) # of flights

2) type of flights

d. diagram of area

e. filing of official Flight Data Forms (Appendix K & L)

f. Compiling Individual Event Score Sheet (Appendix O)

g. listing of special equipment

1) measuring tape

2) scale

3) computation formulas

4) signs and charts

5) tables

5. Review all preliminary preparations with each group.

6. Designate group leaders and responsibilities.

7. Provide for emergencies and special displays.

a. teacher made models

1) U-control

2) radio control

3) guest demonstration by parent or flight club representative

8. Provide First Aid Kit for students and aircraft

9. Have alternative place in case of rain, once on the field

a. museum visit

b. Armory Hall for indoor contests

10. Arrange for lunch and supervised recreation area after lunch.

9617

11. Recheck bus, parents, para-professionals, parental and school approval one or two days before trip.

12. Discuss General Rules and Regulations for trips with students. See school regulations.

13. Requirements for carrying airplanes on bus

    a. shopping bags

    b. boxes

    c. field caddy

14. Prizes and Awards

Field Organizations

Constant attention and alert supervision are required at the field during the entire day on the part of all adults.

1. On the bus, check attendance and review Rules and Regulations with students.
2. Determine that each student's equipment and lunch is safely abroad.
3. Make sure all special equipment is on board.
4. Review Field Organization and distribute printed schedule and diagram of area. Indicate limits of students' use. Indicate safety factors and responsibility for public or private property. Be sure each student knows what he is to do, where he is to do it and when it is to be done.
5. At the field, organize first events and groups.
6. Provide tables (folding, bridge) for special equipment and judges.
7. Distribute prepared event sheets to judges and aides.
8. Distribute necessary equipment
9. Provide measured and calculated information

    a. weather

1) temperature

2) humidity

3) wind direction and speed

4) measuring sticks and tapes

5) stop watches

6) scales

7) pencils

10. Move from one event to another as soon as events are finished. More than enough events should be planned.

11. Check attendance periodically.

12. Provide First Aid for damaged craft.

a) quick setting glue

b) extra balsa parts

c) tape

d) staples and screws

e) strings

f) rubber bands

g) propellers

h) fuel and extra batteries

13. Following morning events, provide a shady area for quiet lunch - toilet facilities - beverage service.

14. Provide books, magazines and supervised free play area for some time after lunch.

15. Special exhibits by teacher or guests may follow lunch.

16. Activities after lunch should be short and of a special nature.

a. additional exhibits by special students

b. run offs of morning contests

c. repeat morning contests of particular interest or with different weather conditions

17. Provide opportunities for picture taking.

18. Check that all contests and events were held.

19. Have students police area.

20. Take attendance on bus before leaving area.

Evaluation

1. Review Flight Data Sheets and Individual Score Sheets for indications that will warrant review and discussion at following class session.

   a. finished models vs. rough wood

   b. craftsmanship compared to performances

   c. effects of weather on flights

   d. calculated and measured performances

2. Discuss and evaluate individual performances.

3. Determine causes of success and failure.

4. Direct students to corrective measures.

5. Award certificates and/or prizes.

MAGAZINES

Nationally distributed (through hobby houses and on newstands) model-aviation and rocket publications are:

Aero Modeller (Model Aeronautical Press, Ltd., 13–35 Bridge St., Hemel Hempstead, Herts., England; distributed in U.S.A. by Eastern News Distributors, 155 West 15 St., New York, N.Y. 10011); all phases of model aviation, contains much material of interest to United States modelers.

American Aircraft Modeler (Potomac Aviation Publications, Inc., 1012 Fourteenth St., N.W., Washington, D.C. 20005); model aviation in all phases, model rocketry.

The Engine Collectors' Journal (bimonthly by the Model Museum, 1235 Xavier St., Denver, Colorado 80204); devoted principally to older model engines which are collectors' items; also some news of old-time model planes, usually termed "antiques."

Flying Models (Rajo Publications, Inc., 215 Park Ave. South, New York, N.Y. 10003) all phases of model aviation.

Model Airplane News (Air Age, Inc., 551 Fifth Ave., New York, N.Y. 10017); all phases of model aviation.

Model Rocket News (Estes Industries, Inc., Box 227, Penrose, Colorado 81240); sent free to customers of this large model-rocket maker; much information on all phases of model rocketry, including plans for successful rockets; concern also issues reports on technical matters of this field.

Radio Control Models and Electronics (Model Aeronautical Press, Ltd., London; available in U.S. from Polk's Model Craft Hobbies, 314 Fifth Ave., New York, N.Y. 10001); covers all sorts of radio-controlled models, much data on building RC equipment; contains much material of interest to United States modelers.

Radio Modeller (Radio Control Publishing Co. Ltd., 64 Wellington Rd., Hampton Hill, Middx., England; available in U.S. from Stanton Hobby Shop Inc., 4734 North Milwaukee Ave., Chicago, Ill. 60630); radio-control models of all types, considerable material on U.S. equipment.

R/C Modeler (R/C Modeler Corp., Box 487, Sierra Madre, California 91024); all phases of radio-control modeling—planes, boats, and so on.

Scale Modeler (Challenge, Inc., 7805 Deering Ave., Canoga Park, California); devoted to construction of nonflying scale models with heavy emphasis on planes and on plastic model construction.

Several of the model-plane and radio magazines presently issue (or have issued in the recent past) annuals covering a variety of subjects in the field. Issues of recent years are available from the same sources and will be found of much interest. Most of the model-plane magazines can provide full-size drawings for the vast variety of planes which have been featured in past issues; they offer free lists of the plans they can supply.

Powerplant Maintenance Technician Curriculum. An Experimental Program for Vocational and Technical High Schools.

New York City Board of Education, Brooklyn, N.Y. Bureau of Curriculum Development.
MF AVAILABLE IN VT-ERIC SET.
Project No. 7516A
PUB DATE - Jul69 88p.

DESCRIPTORS - *VOCATIONAL EDUCATION; *EXPERIMENTAL CURRICULUM; *CURRICULUM GUIDES; *MAINTENANCE; *AVIATION TECHNOLOGY; HIGH SCHOOLS; TECHNICAL EDUCATION; EXPERIMENTAL PROGRAMS; CURRICULUM

ABSTRACT - Intended for vocational and technical high schools, these experimental curriculum materials In powerplant maintenance were prepared by the City of New York Bureau of Curriculum Development in cooperation with the Bureau of Trade and Technical Education. Contents are: (1) Introduction, (2) Topical Outline, Year Level, and Time Allotment, (3) Curriculum Patterns, (4) Student Hours of Instruction, (5) General Notes, (6) Powerplant Maintenance Technician Curriculum, (7) Instructional Facilities, (8) Instructional Equipment, and (9) Teachers. The topics are presented in outline form according to subjects. (GB)

1. INTRODUCTION

The New York City Board of Education Curriculum Development Bureau submits the amended curriculums for Airframe, Powerplant and Airframe and Powerplant Maintenance Technician Ratings to the Department of Transportation, Federal Aviation Administration for approval in accordance with the revised F.A.R. Part 147. The individual curriculum projects are identified as follows:

1. Airframe Maintenance Technician Project 7515
2. Powerplant Maintenance Technician Project 7516
3. Airframe and Powerplant Maintenance Technician Project 7516A

These curriculums will be put to use in those Vocational and Technical High Schools that wish to provide the educational opportunities necessary for teaching the technologies and skills required by interested and motivated students in order to qualify for an F.A.A. Maintenance Technician Certificate of Competency with the Airframe, Powerplant or combined Airframe and Powerplant ratings.

The New York City School System has the following schools teaching F.A.A. Approved Maintenance Technician Curriculums:

1. Aviation High School
   Mr. Frank Woehr, Principal
   Queens Boulevard and 36 Street
   Long Island City, N.Y. 11101

   a) Airframe Maintenance Technician

   b) Powerplant Maintenance Technician

   c) Airframe and Powerplant Maintenance Technician

2. East New York Vocational and Technical High School
   Mr. Solomon Kantowitz, Principal
   1 Wells Street
   Brooklyn, New York, 11208

   a) Powerplant Maintenance Technician

Approval of these curriculums and the issuance of amended F.A.A. Maintenance Technician School Ratings for Aviation High School and East New York Vocational and Technical High School is hereby applied for:

3. CURRICULUM PATTERN

All students enrolled in the FAA approved school curriculum, Airframe or Powerplant, follow the same course of instruction during the 10th and 11th school year.

The course content includes those subjects of common interest and importance to both the Airframe and Powerplant ratings. This pattern of instruction allows the student to acquire experience and training in both areas of the maintenance technician curriculum. He is then better prepared to select the technician rating curriculum. Specialization for either the airframe or powerplant rating takes place in the 12th year.

The FAA approved Airframe or Powerplant maintenance technician curriculum of the school provides 1518 hours of training and instruction for each course. The minimum hours of instruction required for either the Airframe or Powerplant approved curriculum as listed in FAR 147.21, is 1150 hours.

_____ School _____ Date

_____ Principal

4. HOURS OF INSTRUCTION

1) Student daily instruction time 6.75 Hours

	Daily	Term	Year
* Shop	3.00	270	540
* Related Technology	.45	67.5	135
** Math, Science, Drawing	.45	67.5	135
Academic	1.30	135.	270
Lunch	.45	--	--

* 3 Hours and 45 minutes per day for the FAA program during the 11th and 12th Year

** An additional 45 minutes of Math, Science and Drawing added to the FAA program in the 10th year.

2) School Term = 90 days

18 weeks - 5 days per week

3) School Year 180 days

36 weeks - 5 days per week

4) F.A.A. Curriculum hours

* 10th year - Shop, Related Technology, Mathematics, Science and Drawing	438 hours
* 11th year - Shop and Related Technology	405 hours
* 12th year - Shop and Related Technology	675 hours
Total Hours	1518

Maximum number of students enrolled is 900

9635

_____ School _____ Date

_____ Principal

5. GENERAL NOTES

A. Federal Air Regulations contained in Volumes I, II, III, IV, V, VI and IX and Parts 1, 11, 13, 21, 23, 25, 27, 29, 33, 35, 37, 39, 41, 43, 45, 47, 49, 65, 91 and 145 will be covered and taught throughout the Airframe, Powerplant, Airframe and Powerplant and the General Curriculum wherever they are deemed applicable.

B. The use and care of tools, equipment, materials, instruments and essential safety instructions will be taught at the appropriate time in conjunction with the demonstration and information lessons throughout the 10th, 11th and 12th year shops.

C. The basic references recommended and to be followed for the instructional and training program will include: AC65-2A - Airframe & Powerplant Mechanics Certification Guide, The General, Airframe and Powerplant Study Text Books now being prepared for sale by the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402, and any other suitable text book that the individual teacher deems satisfactory. There will be no attempt to restrict or limit the use of texts, instruction sheets, job sheets, information sheets, assignment sheets, audio, visual or animated instructional aids.

_____ School _____ Date

_____ Principal

D. The instructional levels to be maintained are clearly defined in AC65-2A as follows:

Level 1. Know - basic facts and principles

Be able to - find information, follow directions and written instructions.

Knowledge of general principles but limited practical application with no development of manipulative skill.

Instruction by lecture, demonstration and discussion.

Level 2. Know and understand - principles, theories and concepts.

Be able to - find and interpret information and perform basic operations.

A high level of skill is not required.

Instruction by lecture, demonstration, discussion and limited practical application.

Level 3. Know, understand and apply - facts, principles, theories and concepts. Understand how to relate to the total operation and maintenance of aircraft.

Be able to - make independent and accurate judgements, perform all operations to a return to service standard

Practical application of general principles to a high degree and development of a sufficient manipulative skill to accomplish return to service.

Instruction by lecture, demonstration, discussion and a high degree of practical application.

_____ School _____ Date

_____ Principal

E. Testing of each student's technical knowledge and competence in performing manipulative skills will be conducted by a series of written examinations and practical performance projects. This testing and evaluation is indicated at the end of each section for each subject area in the curriculum. This program will consist of the following:

All level 1 learning - a written examination

All level 2 learning - a written examination and a practical project.

All level 3 learning - a written examination and a practical work project that must meet "return to service standard."

The curriculum lists the practical work projects that will be used to conduct the performance demonstrations.

A record of the examination grades and performance scores earned by each student, the practical projects completed by each student, will be kept by the school and made a part of each student's accumulative record. A work progress card will be maintained by the shop teacher, who will hold an FAA Maintenance Technician's Certificate of Competency, for each student that will show:

(a) each completed practical project

(b) grade earned for each project

(c) score earned for each written examination

(d) attendance and punctuality record

(e) character and personality ratings.

_____ School Date

_____ Principal

F. The school will expect each student who satisfactorily completes the FAA Technician Certification Courses, Airframe or Powerplant, to score 70% or higher in the school administered Final Qualifying Examination to be given at the very end of the completed course of study. Failure to meet this standard will prevent a student from receiving the school FAA course completion graduation certificate. Provisions for continued education and training will be made available during the summer period so that interested and motivated students will be helped to meet the requirements for the FAA school course completion graduation certificate.

_____ School

_____ Principal

6. POWERPLANT MAINTENANCE TECHNICIAN CURRICULUM

I. GENERAL CURRICULUM SUBJECTS

A. BASIC ELECTRICITY (10th, 11th, 12th Year and RT)

1. Measure capacitance and inductance (Level 1)

a) The effect of inductive reactance in an electrical circuit.

b) The interrelationship of capacitive and inductive reactance.

c) The term that describes the combined resistive forces in an A.C. electrical circuit.

d) The unit of measurement for capacitance and inductance.

A written examination appropriate to the above subject will be used to determine the degree of learning by the students.

2. Calculate and measure conductivity and electrical power (Level 2)

a) Determine the power furnished by a generator to an electrical system consisting of various electrical units having specific load ratings.

b) Determine the power required by an electric motor that is operating at a specified efficiency and load.

A written examination required and practical projects.

1) Find the power required of a generator supplying various units in an electric circuit.

2) Find the power required by an electric motor in an existing circuit under various load conditions.

School _____ Date _____

Principal _____

c) The current relationship in a electrical parallel circuitry.

d) The unit of measurement used to express electrical power.

e) The principles of electromagnetic induction.

f) The characteristics of magnets and magnetic lines of force.

g) The factors that effect the voltage drop in an electrical conductor.

h) Determine the resistance of an electrical device from the wattage and voltage valves specified.

i) Calculate the voltage drop across a resistor.

A written examination required and practical projects.

1) Determine the needs of, select, install, operate, and test an electrical circuit using a 24V supply consisting of the following units: bus, circuit breaker, switch, relay, lamps, and rheostat. The above project should reflect both series and parallel lamp circuits.

5. Read and interpret electrical circuit diagrams. (Level 3)

a) Trace electrical circuits using aircraft wiring diagrams.

b) Identify electrical system malfunctions by reference to circuit diagrams.

c) Identify the commonly used aircraft electrical symbols.

_____ School _____ Date

_____ Principal

3. Measure voltage, current, resistance, continuity, and leakage (Level 3).

   a) Use an ohmeter to check for open or short circuits.

   b) The test instruments used to check continuity.

   c) The basic operating principles of D.C. electrical instruments.

   d) The basic operating principles of a galvanometer.

   e) Connect voltmeters and ammeters into an electrical circuit.

   f) The purpose of a shunt resistor when used with an ammeter.

   g) The meaning of prefixes such as micro, mega, kilo, and milli as used in expressing electrical quantities.

   A written examination required and practical projects.

      1) Use an ohmmeter to check for short and open circuits in an existing electrical circuit.

      2) Connect an ammeter and a voltmeter in an existing electrical circuit. Use an ammeter requiring an external shunt.

4. Determine the relationship of voltage, current, and resistance in electrical circuits. (Level 3)

   a) Determine the current flow in an electrical circuit using variable resistance and voltage valves.

   b) Determine the power requirements of an electrical circuit when the voltage and resistance valves are specified.

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Wire an aircraft navigation and lighting system mock-up. Using an aircraft wiring diagram incorporate the following units into the lighting system: bus bar, circuit protecting devices, switches, lamps in parallel, variable resistance in series with cabin lamps.

6. Inspect and service batteries (Level 3).

a) Remove spilled electrolyte and treat all adjacent surfaces.

b) Remove and install a battery in the aircraft with a single wire electrical system.

c) Connect batteries to a constant current battery charger.

d) Determine the specific gravity of the battery electrolyte.

e) Perform a high-rate discharge condition test of batteries.

f) The design factors that affect battery voltage and capacity.

g) The factors that determine battery charging rate on a constant voltage source.

h) The indications of a shorted battery cell.

i) The significance of battery capacity ratings.

j) The effects of increased internal resistance on battery operation.

k) The effects of connecting battery cells in series or parallel.

l) The relative advantages of lead-acid and nickel-cadmium batteries for use in aircraft.

School _____ Date _____

Principal _____

m) The principles of battery construction.

n) Check battery electrolyte level.

o) The relationship between battery state of charge and the temperature at which the electrolyte will freeze.

p) The purpose of and requirements for ventilating batteries and battery compartments in civil aircraft.

q) The effect of excessive charging rates on batteries.

A written examination required and practical projects:

1) Remove, clean, service, charge and install batteries in an aircraft. (Use constant current and constant potential charger).

2) Clean and protect battery compartment in an aircraft and service spill-jar.

B. AIRCRAFT DRAWINGS (10th, 11th, 12th Year and RT)

1. Use drawings, symbols, and schematic diagrams. (Level 2)

a) Interpret the various types of lines employed in blueprints and schematics.

b) Use schematic diagrams to analyze system malfunctions.

c) Extract a specific electrical circuit from a system drawing.

d) Know why dimensions are used and how they are shown on aircraft drawings.

e) Use installation diagrams to locate and identify components.

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Install a rotating beacon on an aircraft using blueprints and wire chart as references.

2) Install wiring for a generating system using schematics, charts, and graphs.

3) Using wiring diagram of an aircraft engine instrument system, isolate a particular system, i.e., fuel pressure system, and proceed to correct fuel pressure system malfunction.

4) Rig a centersection on a biplane using specifications shown on a blueprint.

5) Layout a drawing to specifications. Transfer layout information to a piece of flat stock. Fabricate fitting.

2. Draw sketches of repairs and alterations (Level 3)

a) Illustrate a major repair or alteration.

b) Use dividers, compass, ruler, T-Square, etc. in the development of sketches of repairs and alterations.

c) Use standard drafting procedures.

A written examination required and practical projects.

1) Recover a control surface, complete form 337 and appropriate records.

School _____ Date _____

Principal _____

2) Repair damage to stressed skin area of fuselage, fill out form 337 and appropriate records.

3) Install an oil cooler on an engine other than that shown on data sheet, fill out form 337 and appropriate records.

3. Use blueprint information (Level 3).

a) The information presented in blueprint title blocks.

b) The common symbols used on aircraft blueprints.

c) Install and modify component parts by reference to blueprints.

d) Identify the changes made to a blueprint.

A written examination required and practical projects.

1) The drafting department curriculum provides adequate time and practice in areas a, b, and d above.

2) Modify a stringer installation by reference to blueprints.

3) Install an electrical oil pressure gauge using installation prints and specifications.

4. Use graphs and charts (Level 3).

a) Determine electric cable size and current carrying capacity.

b) Determine engine power requirements.

A written examination required and practical projects.

School _____ Date _____

Principal _____

1) By referring to the electrical cable chart in AC43.13-1 determine the size of an aluminum cable to replace a copper cable for the inverter.

2) During ground run use the manufacturer's manual to determine if the engine meets manufacturer's requirements.

C. WEIGHT AND BALANCE (12th Year and RT)

1. Weigh aircraft (Level 2)

a) Use aircraft specifications for weighing purposes.

b) Locate jacks and scales in the correct position.

c) Prepare aircraft for weighing.

A written examination required and practical projects.

1) Weigh an aircraft and record the scale readings.

2. Perform complete weight and balance check and record data. (Level 3)

a) Determine that the foreward or rearward center of gravity (C.G.) limit is not exceeded on a specified aircraft.

b) The point of reference for all weight and balance measurements.

c) The procedure for computing "minimum fuel."

d) Locate the information that should be known to compute weight and balance.

e) The method of expressing additions or removals of equipment for weight and balance purposes.

f) Determine the fully loaded center of gravity of an aircraft.

_____ School _____ Date

_____ Principal

g) Determine the "maximum authorized weight" of an aircraft.

h) The method of determining aircraft empty weight, when engine oil and hydraulic fluid are contained in supply tanks.

i) The effect on weight and balance of replacing a component with another of different weight and location.

j) Calculate the maximum cargo or baggage weight that can be carried by an aircraft.

k) The record requirements for weight and balance data.

l) The hazards of exceeding aircraft fore and aft center of gravity limits.

m) The critical conditions of helicopter load and balance.

n) Determine aircraft empty weight and empty weight center of gravity.

o) Define maximum gross weight.

p) Determine the moment of an item of equipment.

q) Account for tare weight when weighing an aircraft.

A written examination required and practical projects.

1) Compute new empty weight, empty weight center of gravity, and useful load. Complete appropriate record requirements.

2) Change or remove equipment from an aircraft, such as propeller, seats, gas tanks, etc. Compute new weight and balance, reflecting a corrected empty weight, empty weight center of gravity, useful load, fore and aft check and correction where necessary. This project must utilize such specifications and references as "Data Sheets" AC43.13-1, and equipment list.

9648

_____ School _____ Date

_____ Principal

D. FLUID LINES AND FITTINGS (11th, 12th Year and RT)

1. Fabricate and install rigid and flexible fluid lines and fittings (Level 3)

a) Single and double-flare tubing.

b) Install military standard (MS) flareless fittings.

c) The significance of the identification stripes that appear on aircraft hose.

d) Fabricate and install beaded tubing.

e) Use lubricants and sealants in the assembly of lines and fittings.

f) Identify flexible hydraulic lines.

g) Install hose clamps.

h) Determine the bend radii for rigid tubing.

i) Fabricate aluminum tubing using standard AN flared tube fittings.

j) Route fluid lines in entryways and passenger, crew, or baggage compartments.

k) Repair metal tube lines.

l) Route fluid lines adjacent to electrical power cables.

m) Install rigid tubing.

n) Select tube flaring tools.

o) Identify AN fitting materials from color designators.

p) The maximum reduction in original outside diameter allowed when bending aluminum alloy hydraulic lines.

q) The procedure to follow if scratches are detected on an aluminum alloy tube.

School Date

Principal

r) The storage requirements for hydraulic hose.

s) Install flexible hydraulic hose.

t) The lubricant used when assembling oxygen fittings.

A written examination required and practical projects.

1) Make up a replacement fluid line (rigid and flexible) and install the line in an aircraft or system mock-up. Use both AN and MS fittings.

2) Repair a rigid fluid line using a union.

E. MATERIALS AND PROCESSES (10th, 11th, 12th Year and RT)

1. Identify and select appropriate non-destructive testing methods (Level 1)

a) The use of radiography in aircraft and component inspection.

b) The use of ultrasonic inspection methods for detecting cracks.

c) The applicability of magnetic particle inspection methods to engine crankshafts.

d) The method for detecting surface cracks in aluminum castings and forgings.

e) The technique for locating cracks in materials when only one side of the material is accessible.

A written examination appropriate to the above subject will be used to determine the degree of learning by the students.

_____ School _____ Date

_____ Principal

2. Perform penetrant, chemical etching, and magnetic particle inspections. (Level 2)

   a) The general procedure for performing magnetic particle inspection.

   b) Demagnetize steel parts after magnetic particle inspection.

   c) Clean parts in preparation for penetrant inspection.

   d) The visual indications of a subsurface flaw or fracture during magnetic particle inspection.

   e) Locate cracks and blowholes in welded assemblies.

   f) The procedure for using dye penetrants.

   g) Distinguish between heat-treated and non-heat-treated aluminum alloys when the identification marks are not on the material.

A written examination required and practical projects.

   1) Using dye-penetrant method of inspection examine suspected areas of an aircraft engine power section.

   2) Using the magnetic particle type of inspection equipment inspect various engine parts, e.g., piston pin, connecting rod, crankshaft and welded assembly.

   3) Using acceptable trade practices distinguish between a heat treated and a non-heat treated piece of aluminum alloy.

   4) Inspect an aluminum propeller blade using the caustic soda etching method.

   5) Inspect a landing gear component by use of magnetic particle equipment.

   6) Inspect an aircraft and/or powerplant aluminum alloy part using the "zyglo" method of inspection.

9651

_____ School _____ Date

_____ Principal

3. Perform basic heat-treating processes (Level 2)

a) The types of aluminum alloys considered to be heat treatable.

b) Anneal copper tubing.

c) The steps in heat treatment of aluminum alloys.

d) The effects of various forms of heat treatment.

e) The effect of incorrect heat treatment on the corrosion-resistant properties of aluminum alloys.

f) Identify the degree of temper for aluminum alloy products from code designators.

g) The effect of heating a metal slightly above its critical temperature, and then rapidly cooling it.

h) The effect of strain hardening on the tensile strength or aluminum alloy.

i) The relationship between tensile strength and metal hardness.

j) Anneal a welded steel part.

A written examination required and practical projects.

1) Remove a copper primer line, anneal, and reinstall.

2) Anneal a welded steel tubing joint or cluster.

3) Heat treat and form an aluminum alloy rib.

4) Heat treat a new machined center punch.

School _____ Date _____

Principal _____

4. Identify and select aircraft hardware and materials (Level 3)

a) Identify aluminum alloys from code designators.

b) Identify steel from code designators.

c) The identification markings of AN standard steel bolts.

d) Identify aircraft cable.

e) The characteristics of a material that affect its ability to be hammered, rolled, or pressed into various shapes.

f) The SAE system of identifying steel.

g) Determine wrought aluminum alloy composition and condition by referring to aluminum codes.

h) Install self locking nuts.

i) Determine the correct length bolt to use.

j) Determine correct torque valves for tightening aircraft nuts and bolts.

k) Determine rivet composition, condition, shape, and dimension by referring to rivet code.

l) Identify materials suitable for use for firewalls and exhaust shrouds.

m) Install castle nuts.

n) The strength characteristics of type "A" rivets.

o) The characteristic of aluminum alloy rivet material that causes some rivets to require several days to reach their ultimate strength.

_____ School _____ Date

_____ Principal

p) Determine that materials used in aircraft maintenance and repair are of the proper type and conform to the appropriate standards.

q) The characteristics of aluminum - clad sheet aluminum alloy.

A written examination required and practical projects.

1) Fabricate an aluminum alloy control surface.

2) During engine overhaul assemble cylinders and torque to proper valve.

3) Install an aircraft control surface using castellated nuts.

4) During engine overhaul install connecting rods using castellated nuts.

5) Replace an aircraft control cable in an aircraft.

6) Replace a propeller governor control cable.

7) Install bolts using self locking nuts during engine overhaul.

8) Install bolts using self locking nuts during replacement of components on aircraft.

9) Select steel and aluminum alloy using code designators in fabricating aircraft fittings and brackets.

10) Make stressed skin repair.

5. Inspect and check welds (Level 3)

a) The characteristics of a good weld.

b) The types of stress that welded joints can withstand.

c) The effect of welding over a previously brazed or soldered j

9654

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Weld a steel tubing cluster.

2) Inspect a welded tube structure, i.e., welded tube engine mount, welded tube fuselage structure.

6. Perform precision measurements (Level 3).

a) Use a micrometer and a caliper to make precision measurements.

b) Measure a small hole using micrometer and a hole gauge.

c) Read and interpret a vernier micrometer scale.

d) Use a dial indicator, V Blocks, and a surface plate to check the alignment of a shaft.

A written examination required and practical projects.

1) During engine overhaul inspect various parts for wear and proper clearance.

2) During engine overhaul inspect a camshaft and/or crankshaft for runout.

F. GROUND OPERATION AND SERVICING (12th Year and RT)

1. Start, ground operate, move, service, and secure aircraft (Level 2).

a) The procedure for extinguishing fires in the engine induction system during starting.

b) Use hand signals to direct aircraft movement.

c) Select and use external auxiliary power units for engine starting.

d) Tie-down and secure aircraft for outside storage.

_____ School _____ Date

_____ Principal

e) Protect aircraft fuel system from contamination during fueling operations.

f) Connect and operate an external source of hydraulic power.

g) Start and operate an engine equipped with a float type carburetor.

h) Check a reciprocating engine for liquid lock.

i) Operate hand and electrical priming systems during engine starting.

j) Start and operate an engine equipped with a pressure injection carburetor.

k) Start and operate an engine equipped with an internal supercharger.

A written examination required and practical projects.

1) Move, tie-down, and store aircraft on hangar apron and in hangar.

2) Pre-start check a reciprocating engine including a check for liquid lock.

3) Start an aircraft engine using an A.P.U.

4) Start and run an aircraft engine with an internal supercharger.

5) Start and run an aircraft engine with a pressure injection carburetor.

6) Start and run an aircraft engine with a float type carburetor.

7) Service an aircraft engine with fuel and oil.

8) Operate aircraft actuating mechanisms with an external source of hydraulic power.

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Clean an engine in preparation for Disassembly.

2) Clean engine parts in preparation for inspection.

3) Clean an aircraft structure in preparation for painting.

4) Clean engine exhaust systems.

2. Perform aircraft cleaning and corrosion control (Level 3).

a) Protect tires and other rubber products from the deteriorating effects of cleaning materials.

b) The cause and corrective procedures for fretting corrosion.

c) Identify and control intergranular corrosion of heat treated aluminum alloy.

d) Protect structure against dissimilar metal corrosion.

e) Prevent and remove rust.

f) The effect of oily, dirty surfaces on the operation of high performance aircraft.

g) Protect interior surfaces of closed steel and aluminum tubing against corrosion.

h) The methods of protecting aluminum alloy parts against corrosion.

i) Clean and protect battery compartments and adjacent areas.

j) Remove corrosion products such as metal flake, scale powder, and salt deposits from aluminum.

k) Clean corrosion resistant parts by blast cleaning methods.

l) Use paints and similar organic coatings for corrosion protection purposes.

_____ School _____ Date

_____ Principal

2. Identify and select fuels (Level 2)

a) The effect of ethylene dibromide added to aviation gasoline.

b) The identifying color of various grades of aviation gasoline.

c) The characteristic of a fuel that affects its tendency to "vapor lock."

d) The significance of the numbers used to designate various grades of aviation gasoline.

e) The relative advantages of gasoline and kerosine for use as fuel for turbine engines.

f) Determine the types of fuel to be used with a specific aircraft.

g) The factors affecting the antiknock characteristics of fuel.

A written examination required and practical projects.

1) Refuel various aircraft requiring several grades of fuel.

G. CLEANING AND CORROSION CONTROL (10th, 11th, 12th Year and RT)

1. Identify and select cleaning materials (Level 3).

a) The effect of caustic cleaning products on aluminum structures.

b) The characteristics and use of chemical cleaners.

c) Clean aluminum and steel engine parts.

d) The type cleaner for use on high strength metals.

e) The methods for cleaning turbine engine compressor blades.

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Clean and protect a battery compartment on an aircraft.

2) Clean exhaust collectors and shrouds.

3) Cover tires of stored aircraft against oil and solvent drippings.

4) Remove rust from the exterior of spark plugs and paint.

5) Wash down aircraft.

6) Clean, zinc chromate, and paint aircraft fittings and brackets before installing.

7) Use par-al-ketone to protect exterior surfaces of engines in storage.

8) During fabrication of a control surface (aileron) use proper corrosion protection between dissimilar metals.

H. MATHEMATICS (10th, 11th, 12th Year and RT)

1. Extract roots and raise numbers to a given power (Level 1).
2. Determine areas and volumes of various geometrical shapes (Level 2).
3. Solve ratio and proportion and percentage problems (Level 3).
4. Perform algebraic operations involving addition, subtraction, multiplication, and division of positive and negative numbers (Level 3).

Students will demonstrate competency with this subject while performing practical projects and written examinations at appropriate times throughout the curriculum. Selected projects would include: weight and balance computations, flat pattern layout development, electric circuit computations, and calculating gear ratios and engine displacement.

_____ School _____ Date

_____ Principal

I. MAINTENANCE FORMS AND RECORDS (11th, 12th Year and RT)

1. Write descriptions of aircraft condition and work performed (Level 3).

   a) Describe the repairs made to an aircraft structure.

   b) State aircraft condition based upon inspection.

   A written examination required and practical projects.

      1) Make a log book entry describing repairs made to an aircraft and/or powerplant. Major and minor repairs.

      2) Perform a 100 hour inspection to an aircraft and/or powerplant and submit a completed inspection report and discrepancy list.

2. Complete required maintenance forms, records, and inspection reports (Level 3).

   a) Enter the required information in the permanent maintenance records when a minor repair has been performed.

   b) Prepare and properly dispose of FAA Form 337.

   c) The minimum information required to be entered in the maintenance records after maintenance or alteration of aircraft.

   d) Make record entries to indicate compliance with airworthiness directives.

   e) The definition of "Time in service" with respect to maintenance records.

   f) The record requirements for returning aircraft to service after 100 hour inspection.

   g) The requirement for maintaining a permanent record of aircraft maintenance.

School Date

Principal

h) The definition of "repair" as related to aircraft maintenance.

i) The requirements for a permanent maintenance record.

A written examination required and practical projects.

1) Make a log book entry reflecting a major repair made to an aircraft and/or powerplant and execute an FAA Form 337.

2) Make a log book entry reflecting compliance with an airworthiness directive.

3) Make a log book entry reflecting return to service after completing a 100 hour inspection.

J. BASIC PHYSICS (10th, 11th, 12th Year and RT)

1. Use the principles of simple machines; sound, fluid, and heat dynamics (Level 2).

The course content includes classroom and laboratory experiments and demonstrations in the theory and application of the laws of physics as applied to aviation in the performance and operation of aircraft and powerplants and the functioning of its support systems. Examples: Charles Law, Boyles Law, Pascals Law, Bernoulli Theorum, Newtons Laws, Otto cycle, braden cycle are examples of the basic concepts incorporated in the curriculum.

_____ School _____ Date

_____ Principal

K. MAINTENANCE PUBLICATIONS (10th, 11th, 12th Year and RT)

1. Select and use FAA and manufacturer's aircraft maintenance specifications, data sheets, manuals, and publications, and related federal aviation regulations (Level 3).

   a) Determine the suitability of a propeller for use with a particular engine - airplane combination.

   b) Determine the minimum diameter of a propeller type and model when used with a particular engine.

   c) Locate aircraft leveline and weighing information.

   d) Determine engine/propeller speed ratios.

   e) The instrument markings required on a specified type and model aircraft.

   f) The purpose and applicability of technical standard orders.

   g) The purpose and applicability of supplemental type certificates.

   h) Identify the useful load and empty weight C.G. of an aircraft by reference to data.

   i) Use FAA specifications and type certificate data sheets.

   j) The applicability and requirements for aircraft airworthiness certificates.

   k) Determine the control surface movement limits of a specified aircraft.

   l) Determine seat locations of an aircraft using aircraft specifications.

   m) Use aircraft listing to find information about aircraft of limited production.

School _____ Date _____

Principal _____

k) Determine the maintenance classification (major repair, minor repair, preventive maintenance) of servicing landing gear shock struts.

l) Determine the repair classification (major repair, minor repair, preventive maintenance) of repairs to steel tubing structures by welding.

m) Determine the repair classification (major repair, minor repair, preventive maintenance) of replacing the fabric on fabric - covered parts such as wings, fuselages, stabilizers, and control surfaces.

n) The recency of experience requirements for certificated mechanics.

o) The privileges of a mechanic regarding return to service of aircraft after major repairs.

p) Determine the maintenance classification (major repair, minor repair, preventive maintenance) of the replacement of aircraft components with new, rebuilt, or repaired components of similar design.

A written examination is required and practical projects.

1) Service a wheel and tire assembly, and/or a controllable pitch propeller; establish authority to do the work necessary. Refer to Part 65. Classify the work required as to a major repair, minor repair, or preventive maintenance. Refer to Part 43.

School _____ Date _____

Principal _____

n) The purpose and applicability of FAA airworthiness directives.

o) Use "table of limits" to determine condition of parts.

A written examination as required and practical projects.

1) During the performance of a 100 hour inspection, determine from the aircraft data sheet that the powerplant and propeller combination is correct, also that the diameter of the propeller is within limits.

2) During the weighting of an aircraft make use of the aircraft data sheets to determine the identification of, and location of the leveling means, seat locations, and gross weight.

3) Check instrument marking and placards using aircraft and powerplant data sheets.

4) During engine overhaul make use of manufacturer's instruction manuals and table of limits.

5) Determine the airworthiness of various pieces of equipment by referring to technical standard orders.

6) During the performance of a 100 hour inspection, refer to summary of airworthiness directives for mandatory adherence data sheets for control surface travel.

2. Read technical data (Level 3)

a) Find specified information in technical reports and manuals.

A written examination required and practical projects will be combined with Item "L" Mechanic Privileges and Limitations.

_____ School _____ Date

_____ Principal

2) Service a landing gear shock strut and/or remove deep dents, cuts, scars or nicks on an aluminum propeller. Establish authority to do the work necessary. Refer to Part 65, and classify the work required as to a major repair, minor repair, or preventive maintenance. Refer to Part 43.

3) Repair a damaged steel tubing structure and/or overhaul a cylinder. Establish authority to do the work necessary. Refer to Part 65 and classify the work required as to a major repair, minor repair or preventive maintenance.. Refer to Part 43.

4) Recover a control surface and/or remove and service a set of spark plugs. Establish authority to do the work necessary. Refer to Part 65, and classify the work required as to a major repair, minor repair or preventive maintenance. Refer to Part 43.

5) Replace a landing gear shock strut and/or a rebuilt generator. Establish authority to do the work necessary. Refer to Part 65, and classify the work required as to a major repair, minor repair or preventive maintenance. Refer to Part 43.

_____ School _____ Date

_____ Principal

II. POWERPLANT THEORY AND MAINTENANCE

A. RECIPROCATING ENGINES (11th, 12th Year and RT)

1. Inspect and repair 14 cylinder or larger radial engine (Level 2).

a) The purpose and advantage of using propeller reduction gearing.

b) The characteristics of thrust bearings used in large radial engines.

c) The characteristics of crankshaft bearings used in large radial engines.

d) The construction characteristics of the crankshaft and rod assemblies for a twin-row radial engine.

e) The loads acting on the power case and nose case of the large radial engine during various conditions of operation.

f) The methods of classifying reciprocating engines.

g) The factors that affect the volumetric efficiency of an engine.

h) Determine the cylinder firing order for various types of engines.

A written examination required and practical projects.

1) Remove, inspect and replace a nose section.

2) Determine the firing order of various types of engines.

_____ School _____ Date

_____ Principal

2. Overhaul reciprocating engine (Level 2)

a) The purpose and operating principles of dynamic dampers used in aircraft engine.

b) The characteristics of various crankshaft designs.

c) The basic operating principles of four stroke cycle engines.

d) The characteristics of various piston pin and knuckle pin retention devices.

e) The processes used to harden cylinder bores.

f) The purpose and applicability of choke-type or taper-ground cylinders.

g) The wear characteristics of engine cylinder walls.

h) The purpose of valve overlap in some engines.

i) The effects of various poppet-type valve face angles.

j) The characteristics of various types of valve operating mechanisms.

k) The operating characteristics of zero-lash hydraulic valve lifters.

l) Time engine valves during engine assembly.

m) Install valve guides.

n) Grind and resurface valve and valve seats.

o) The purpose of using relatively large piston-to-cylinder wall clearances in aircraft engines.

p) The indications of failed or failing engine bearings.

_____ School _____ Date

_____ Principal

q) The result of operating an engine at high power settings before the lubricating oil has come up to operating temperature.

r) Check piston rings for correct end and side clearance.

s) Check valve stems for stretch.

t) Repair a scored aluminum piston.

u) Perform crankshaft "runout."

v) Prepare engine for disassembly before overhaul.

w) Measure inside diameter, taper, and out-of-round of a cylinder bore.

x) Install cylinders and tighten hold-down nuts.

y) The construction characteristics of air-cooled engine cylinders.

z) The construction characteristics and the operating principles of poppet-type engine valves.

aa) The construction of aircraft engine pistons.

bb) The types and arrangements of piston rings used in aircraft engines.

cc) The purpose of using more than one spring on aircraft engine valves.

dd) The operating principles and construction of spur and pinion-type and planetary type propeller reduction gearing.

ee) The principles of construction and operation of accessory gear drive trains on reciprocating engines.

ff) Inspect cast and forged engine crankcase assemblies.

gg) Remove and install studs in engine crankcase and accessory sections.

A written examination required and practical projects.

1) Overhaul a reciprocating engine.

_____ School _____ Date

_____ Principal

3. Inspect, check, service, and repair opposed and radial engines and reciprocating engine installations (Level 3).

   a) Check and adjust engine valve clearances.

   b) Determine the speed and direction of rotation of the cam ring in various radial engines.

   c) The effect of excessive or insufficient valve clearances on engine operation.

   d) The relationship between operating valve clearances and cold valve clearances.

   e) Perform cylinder compression tests.

   f) Perform an ignition system operational check.

   g) Determine the condition of cable-operated engine control systems.

   h) Check and adjust engine idling speed and mixture.

   i) Detect and determine the cause of a "cold" cylinder.

   j) The purpose of establishing one or more critical ranges for certain engine-propeller combinations.

   k) The operating indications of a worn or weak engine.

   l) The effect of a leaking oil dilution valve on engine operation.

   m) The effect of a low oil supply on engine operation.

   n) The indications of a correctly functioning engine oil system.

   o) The probable cause of oil being thrown out of the breather of wet-sump engine.

   p) Determine the source and cause of metallic particles found on the oil screen.

School _____ Date _____

Principal _____

q) The effect of an unbalanced propeller on engine operation.

r) The power setting most desirable for protracted engine operation.

s) Dilute engine oil in preparation for cold weather starting operations.

t) The purpose and operation principles of engine dynamic suspension systems.

u) Install and time a magneto.

A written examination required and practical projects.

1) Inspect, service, and repair opposed and radial engines.

2) Inspect, service and repair reciprocating engine installation.

3) Install reciprocating engine.

4. Install, troublesheet, and remove reciprocating engines (Level 3).

a) The effect of throttle position upon fuel-air.

b) Pre-oil an overhauled engine before starting.

c) Install air-cooled engine baffles.

d) The method of hoisting or lifting engines during removal and installation.

e) The effect of increased engine manifold pressure on master rod bearing load.

f) The effect of air density on engine power output.

g) The causes of engine backfire.

h) The basic operational sequence for increasing or reducing the power output of an engine equipped with a constant-speed propeller.

School Date

Principal

i) The factors that affect an engine's tendency to detonate.

j) The effect of induction system air leaks on engine operation.

k) The indications of a leaking primer system during engine operation.

l) The effect of exhaust back pressure on engine power output.

m) The result of incorrect fuel-air mixture adjustments.

n) The indication and effect of carburetor icing.

o) Operate and adjust mechanical push-pull control system.

A written examination required and practical projects.

1) Install, troubleshoot, and remove reciprocating engine.

2) Operate installed powerplant, adjust controls, check performance to conform with operation manual.

B. TURBINE ENGINES (11th, 12th Year and RT)

1. Overhaul turbine engine (Level 2).

a) The relationship between rotor speed and total thrust of a turbine engine.

b) The relationship between turbine inlet temperature and thrust of a turbine engine.

c) The relationship between operating altitude and thrust of a turbine engine.

d) The operating characteristics of turbine engines equipped with two-spool or "split" compressors.

_____ School _____ Date

_____ Principal

e) The operating characteristics of fan and bypass turbine engines.

f) The relative gas pressures in various portions of a turbine engine.

g) The function of the nozzle diaphragm in a turbine engine.

h) The function of the exhaust cone in a turbine engine.

i) The operating characteristics and types of combustion chambers.

j) Remove and install outer combustion chamber case and liners.

k) The methods for disassembling compressor.

l) The function and location of fuel nozzles.

A written examination is required and practical projects.

1) Inspect nozzle diaphragm for cracks, distortion and failure.

2) Remove and inspect the exhaust cone for cracks, damage, or failure to welds and replace.

3) Remove combustion chambers from engine. Remove inner liner and inspect for cracks, burned areas and cross over tubes for excessive heat damage.

2. Inspect, check, service, and repair turbine engine installations. (Level 2)

a) The principles of operation of thrust reversing systems used with turbine engines.

b) The advantages of a gas turbine geared to a propeller.

c) The types of compressors most commonly used in turbine engines.

School Date

Principal

d) The construction and operating characteristics of axial-flow compressors.

e) The advantages of the axial-flow compressor over the centrifugal compressor.

f) The function and location of the diffuser section.

g) The basic design of turbine blades.

h) The effect of high ambient temperatures on turbine engine operation.

i) The type failures to which turbine components are subject.

j) The results of excessive operating temperature.

A written examination is required and practical projects.

1) Remove upper compressor case and inspect for damaged blades, nicks and distortion.

2) Remove, install and connect engine controls in a jet aircraft.

3. Install, troubleshoot, and remove turbine engines (Level 2)

a) The operating principles of a turbine engine.

b) The effect of air density on the thrust of a turbine engine.

c) The effect of exhaust nozzle adjustments on turbine engine operation.

d) The method of controlling compressor surge.

e) The purpose and operation of fuel control devices.

f) The cause of hot spots on the outer combustion casing.

School _____ Date _____

Principal _____

g) The method of insuring ignition in combination chambers not equipped with igniter plugs.

h) Adjust turbine engine fuel controls.

A written examination is required and practical projects.

1) Install exhaust nozzle, check clearance between turbine blade tip and exhaust nozzle.

2) Remove, inspect, replace and adjust controls for fuel control unit. Trim engine.

C. ENGINE INSPECTION (11th, 12th Year and RT)

1. Perform powerplant conformity and airworthiness inspections (Level 3).

a) Determine that applicable airworthiness directives are complied with.

b) Determine that the powerplant conforms with the applicable FAA specification.

A written examination is required and practical projects.

1) Students will perform powerplant conformity and airworthiness inspection as part of the 100 Hour inspection.

School _____ Date _____

Principal _____

III. POWERPLANT SYSTEMS AND COMPONENTS

A. ENGINE INSTRUMENT SYSTEMS (11th, 12th Year and RT)

1. Troubleshoot, service, and repair fluid rate-of-flow indicating systems (Level 2).

a) The purpose and operating principles of a fuel-flow indicating system.

b) The relationship between fuel flow and the power output of an engine.

A written examination is required and practical projects.

1) Trace and troubleshoot the electrical wiring for a fuel flow indicating gauge and transmitter.

2. Inspect, check, service, troubleshoot, and repair engine temperature, pressure, and RPM indicating systems (Level 3).

a) The operating principles of thermo-couple-type temperature indicating systems.

b) The effect of a broken or leaking manifold pressure gauge line.

c) The operating principles of engine oil temperature indicating systems.

d) The purpose and operating principles of a manifold pressure indicating system.

e) The operating principles of engine oil temperature indicating systems.

f) Apply markings to the glass face of engine instruments.

g) Install tachometer drives.

h) Determine the reason for failure of an electric tachometer system.

9676

School _____ Date _____

Principal _____

i) The requirements for a carburetor air temperature indicating system.

j) Determine the reason for an off-scale reading of a ratiometer-type indicating system.

k) Determine the cause of erratic indications when using a thermo-couple system.

l) The purpose and operating principles of fuel pressure warning systems.

m) The installation practices for thermo-couple leads.

n) The operation and use of synchronous motors.

o) Measure the resistance of thermocouple leads.

p) Determine the cause of an inverse reading in a thermocouple temperature indicating system.

q) Identify the types and application of thermocouples used to indicate turbine engine temperatures.

A written examination is required and practical projects.

1) Inspect, check, service, troubleshoot and repair engine temperature, pressure and tachometer (RPM) indicating systems.

B. ENGINE FIRE PROTECTION SYSTEMS (12th Year and RT)

1. Inspect, check, service, troubleshoot, and repair engine fire detection and extinguishing systems (Level 3).

a) Check continuity and resistance of the electrical circuit.

b) Determine the causes of system malfunction.

School _____ Date _____

Principal _____

c) The methods used to release the extinguishing agent.

d) The sensing devices used in the detection systems.

A written examination is required and practical projects.

1) Inspect, check, service, troubleshoot and repair engine fire extinguishing systems.

C. ENGINE ELECTRICAL SYSTEMS (10th, 11th, 12th Year and RT)

1. Repair engine electrical system components. (Level 2)

a) Check the condition of shunt and compound generator field circuits.

b) Locate and use overhaul information for electrical equipment.

c) The procedures for correcting generator brush arcing.

d) Check a motor or generator armature to determine that the windings are not grounded.

e) Smooth the commutator surface of a motor or generator armature.

f) Determine the cause of solder deposits on the armature cover plate of a generator.

g) The purpose of a ripple filter in a generator power circuit.

h) The type of electric motor used with direct-cranking engine starters.

i) The types of voltage regulators used with high output direct current generators.

j) The results of short or open circuits in a generator control circuit.

k) The effect of sticking points in a reverse-current cutout relay.

_____ School _____ Date

_____ Principal

l) The method of providing and controlling the field current of aircraft generators.

m) The methods of controlling parallel direct current generators.

n) The methods used to control output frequency and voltage of alternating current generators.

o) The methods of reducing armature reaction in aircraft generators.

p) The methods of controlling current and voltage output of compound direct current generators.

q) The operating principles of carbon-pile voltage regulators.

r) The operating characteristics of series-wound direct current electric motors.

s) The purpose and operation of reverse-current cutout relays in generator control circuits.

t) The general operating characteristics of vibrator-type current and voltage regulators.

u) Flash a generator field.

v) The effect of changes in speed and load on generator output.

w) The design factors that determine the number of cycles per revolution an alternating current generator will produce.

x) The factors that effect the torque produced by an electric motor.

y) The function of a commutator in a direct current electric motor.

z) Determine the output frequency of an alternating current generator.

aa) The methods used to protect armature shafts from overloads.

bb) Seat new or replacement generator brushes.

cc) The effect of incorrect generator brush spring tension on generator operation.

_____ School _____ Date

_____ Principal

dd) The speed and load characteristics of series, compound, and shunt-wound electric motors.

ee) The basic principles of electric generators.

ff) The basic internal electrical circuits of series, compound, and shunt-wound generators.

gg) The applicability and use of intermittent duty electric motors.

hh) The operating principles of magnetic clutches and brakes commonly used with electric motors.

ii) The requirements and methods for controlling a malfunctioning generator.

jj) The purpose and operation of reversible electric motors.

A written examination is required and practical projects.

1) Overhaul and functionally test a D.C. generator.

2) Remove and overhaul a flap actuator motor.

3) Install and perform an operational check of an alternator.

4) Troubleshoot and correct alternator failure.

5) Troubleshoot an inoperative inverter.

6) Troubleshoot output of a transformer rectifier unit.

140 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

_____ School _____ Date

_____ Principal

2. Install, check, and service engine electrical wiring, controls, switches, indicators, and protective devices. (Level 3)

   a) The purpose, applicability, and operation of electrical fuses and circuit breakers.

   b) The types of electrical switches and their operation.

   c) Install and wire electrical switches.

   d) Splice wiring in engine electrical systems.

   e) The characteristics of high-tension and low-tension electrical wiring.

   f) The purpose, applicability, and use of electrical wiring terminal strips.

   g) The criteria for selecting aluminum and copper electrical cables.

   h) Replace terminals on aircraft aluminum and copper electrical cables.

   i) Types of switches and circuits used to control reversible electric motors.

   j) Identify aircraft electric cables.

   k) Determine the current-carrying capacity of an electrical circuit.

   l) Install electrical wiring in conduits.

   m) Use electric cable selection chart for determining the correct cable to use in specified circumstances.

   n) The strength requirements for electric cable terminals.

   o) Select and install electrical bonding jumpers.

   p) The installation and wiring of solenoid operated switches.

School _____ Date _____

Principal _____

q) The characteristics of single-wire electrical systems.

r) The use of quick-disconnect electrical plugs and sockets.

s) The American Wire Gauge (A.W.G.) system of designating electrical wire sizes.

t) The cause and effect of solenoid switch chatter.

u) The method of providing direct current for battery charging on aircraft that operate only alternating current generators.

v) The maximum permissible continuous load on the electrical system.

w) The sources of alternating current power in aircraft that operate only direct current generators.

x) The operating principles and characteristics of transformers.

y) Determine the approximate continuous load on an aircraft electrical system.

A written examination is required and practical projects.

1) Wire A.C. and D.C. electrical system mock-up.

2) Inspect, service and trouble shoot A.C. and D.C. generator regulating system.

3) Inspect, service and troubleshoot an engine starting system.

4) Install and adjust the limit switches for various actuators; example: cowl flaps and oil cooler door actuators.

School _____ Date _____

Principal _____

5) Check 3 phase alternators for proper phasing in parallel installation on a bus.

6) Connect the alternator and adjust the voltage and frequency output.

D. LUBRICATION SYSTEMS (11th, 12th Year and RT)

1. Identify and select lubricants (Level 2)

a) The desirable characteristics for aircraft engine lubricating oils.

b) The meaning and importance of oil viscosity.

c) The meaning and significance of oil flash point.

d) The purpose of using synthetic lubricants for turbine engines.

e) The effect of heat on lubricants.

f) The grade designations for aviation oils.

g) The designations for synthetic turbine oil.

h) The results of operating an engine using an incorrect lubricant.

i) The functions of engine oil in addition to lubricating the engine.

A written examination is required and practical projects.

1) Service the lubricating system.

2) Adjust the oil pressure relief valve.

2. Repair engine lubrication system components (Level 2)

a) Clean and repair aluminum alloy external oil lines.

b) Clean external lubrication system components.

c) The function and location of an oil temprature regulator.

d) The size requirement for the oil inlet line.

School _____ Date _____

Principal _____

e) Clean and test oil tanks.

f) The purpose and operation of the oil cooler.

g) The operating principles of lubrication pumps.

A written examination is required and practical projects.

1) Clean and repair aluminum alloy external oil lines.

2) Clean and test oil tanks.

3) Install an oil line from the tank to the inlet of the pump.

4) Remove, disassemble, inspect, and replace the engine oil pump.

3. Inspect, check, service, troubleshoot, and repair engine lubrication systems (Level 3).

a) Determine source and cause of metallic particles in the lubricating oil.

b) The purpose and principles of operation of engine oil dilution systems.

c) The expansion space requirements for engine oil supply tanks.

d) The purpose for changing engine lubricating oil at specified intervals.

e) The type of lubrication system generally used in high volume reciprocating engines.

f) The factors that effect the oil consumption of a reciprocating engine.

School _____ Date _____

Principal _____

g) The method normally used to prevent excessive oil from accumulating in the cylinders of inverted engines or the lower cylinders of radial engines.

h) The method of controlling the oil film on cylinder walls.

i) The method of lubricating the valve-operating mechanism in an overhead-valve engine.

j) The venting requirements of dry-sump and wet-sump engine lubrication systems.

k) The effect of broken or leaking lines in various parts of the lubrication system.

l) The effect of engine wear on the operation of the lubrication system.

m) The operating indications of a low engine oil supply.

n) The method of maintaining a reserve supply of oil in the engine oil supply tank for use in propeller feathering.

o) The requirements for marking oil tank fillers.

p) The purpose and operating principles of the lubrication system pressure-relief valve.

q) The purpose and operation of the oil cooler bypass valve.

r) The effect of congealed oil in the heat exchange portion of an oil radiator.

s) The purpose, location, and operation of anti-sludge chambers in the lubrication system of a reciprocating engine.

_____ School _____ Date

_____ Principal

t) The purpose and operation of the bypass feature built into most engine oil filtering systems.

u) The operating principles of the stacked disc, edge filtration type of filter.

v) The characteristics and operating principles of dry-sump and wet-sump engine lubricating systems.

w) The purpose, location, and operation of the oil separator.

x) Adjust engine oil pressure.

y) The purpose of the restricted orifice in the oil pressure gage line.

z) The effect of obstructed rocker box inter-cylinder oil drain lines on engine operation.

aa) The characteristics and principles of operation of a radial engine oil scavenging system.

A written examination is required and practical projects.

1) Remove, clean, inspect and replace main oil screen and disc type filter.

2) Install and fit various ring combinations on pistons.

3) Placard engine oil tank fillers.

4) Adjust oil pressure relief valve.

5) Clean and service oil cooler and by-pass valve.

6) Fabricate an oil pressure gauge line and check snubber.

7) Clean oil sludge chambers in a crankshaft.

8) Disassemble, clean, inspect and measure a scavenger pump.

School _____ Date _____

Principal _____

E. IGNITION SYSTEMS (11th, 12th Year and RT)

1. Overhaul magneto and ignition harness (Level 2).

a) The construction characteristics of magneto main case housings.

b) The characteristics and construction materials of magneto pole shoes or coil core extensions.

c) The purpose and methods of ventilating aircraft magneto housings.

d) The materials used in the construction of magneto breaker points.

e) The purpose and use of "keepers" placed across the poles of a rotating magnet that has been removed from a magneto.

f) Check the strength of a rotating magnet installed in a magneto.

g) Internally time a magneto during assembly.

h) Determine the rotational speed of a magneto when installed on various types of engines.

i) The purpose and location of condensers in a magneto electrical circuit.

j) Determine the condition of magneto breaker points by visual indications.

k) Lubricate a magneto breaker cam.

l) The effect of cam-follower wear on pivot and pivotless type breaker point assemblies.

m) The meaning of the term "E-Gap Angle."

n) The characteristics of the rotating magnets commonly used in aircraft magnetos.

o) Install and adjust breaker points.

_____ School _____ Date

_____ Principal

p) The characteristics of cams used in aircraft magnetos to operate the breaker points.

q) The purpose of setting ignition cables in a plastic insulating material within some ignition harnesses.

r) Install high-tension ignition cables in a shielded ignition manifold.

s) The purpose and operation of impulse couplings used with aircraft magnetos.

t) The results of operating a magneto with a broken impulse coupling spring.

u) The methods used to secure ignition leads in harnesses and distributor blocks.

v) Measure breaker point spring tension.

A written examination is required and practical projects.

1) Overhaul, inspect and functionally test a magneto.

2. Repair engine ignition system components (Level 2).

a) The purpose and operation of magneto breaker points.

b) Measure the capacity of a condenser.

c) Check ignition coil windings for shorts or open circuits.

d) Locate and use data associated with ignition system components.

e) The effect of weak magnets on engine operation.

f) The effect of weak breaker point spring tension on engine operation.

g) Clean and inspect spark plugs and igniter plugs.

_____ School _____ Date

_____ Principal

h) Adjust spark plug electrodes.

i) The precautions to observe when working with high-energy ignition systems.

j) Determine that a distributor is internally timed.

k) The effect of high resistance in an ignition lead on engine operation.

l) The function and characteristics of ignition harnesses.

m) Determine the continuity of ignition wiring.

n) The construction and operation of a transformer coil for low-tension ignition systems.

A written examination is required and practical projects.

1) During magneto overhaul inspect and measure the capacity of a condenser.

2) During magneto overhaul locate and use data associated with ignition system components.

3. Inspect, check, service, troubleshoot, and repair reciprocating and turbine engine ignition systems. (Level 3).

a) The purpose of shielding aircraft engine ignition systems.

b) The purpose and principles of staggered ignition timing.

c) Install and time an ignition system distributor.

d) Recognize and interpret basic ignition analyzer patterns.

e) The purpose and operating principles of spark advance systems.

f) The effect of using condensers of incorrect capacity in an ignition system.

_____ School _____ Date

_____ Principal

g) The operating principles of low-tension ignition systems.

h) The effect a shorted primary winding in a low-tension ignition coil has on engine operation.

i) Install and test magneto ignition switches.

j) Test an ignition harness for electrical leakage.

k) The purpose and principles of compensated ignition timing.

l) The operating periods of turbine engine ignition systems.

m) The results of using a spark plug of incorrect heat range in an engine.

n) Install and remove spark plugs.

o) The meaning of "reach" as applied to spark plug design.

p) Inspect spark plugs for damaged insulation.

q) The cause and effect of various types of spark plug fouling.

r) The purpose and operation of an ignition booster system.

s) The purpose and operation of an induction vibrator.

t) Install and time a magneto equipped with an impulse coupling.

A written examination is required and practical projects.

1) Replace a defective wire in an ignition harness.

2) Clean, inspect and test a set of spark plugs.

3) Bench time a magneto.

4) Hi-potential test the ignition harness for shorts and continuity.

5) Install and time a distributor for a low and high tension ignition system.

6) Install and wire an ignition switch.

School _____ Date _____

Principal _____

7) Remove, inspect and install a set of spark plugs.

8) Install and time a magneto.

9) Remove, inspect and install a jet engine igniter.

F. FUEL METERING SYSTEMS (11th, 12th Year and RT)

1. Inspect, check and service water injection systems (Level 1).

a) The purpose and effect of injecting water or water-alcohol during periods of high engine power output.

b) The means used to prevent the freezing of the water or ADI liquid.

c) The effect of atmospheric humidity on engine power when using water injection.

d) The effect of exhausting the water supply during take off operations utilizing water injection.

e) The purpose and effect of the derichment valve in the water-alcohol injection system.

f) The results of detonation within an engine.

g) The procedure to follow when detonation occurs.

h) The factor that determines the amount of water flow during ADI operation.

i) The method for preventing corrosion of lines and fittings.

j) The purpose of the oil-pressure operated valve in the ADI system.

A written examination appropriate to the above subject will be used to determine the degree of learning by the students.

_____ School _____ Date

_____ Principal

2. Overhaul carburetor (Level 2).

a) The fuel metering forces of a conventional float-type carburetor and a pressure-type carburetor.

b) The relationship between carburetor venturi size and engine displacement volume.

c) The fuel-air mixture requirements of an engine during idling and during high power setting.

d) The operation of the idling system of a float type carburetor and a pressure-type carburetor.

e) The effect of a clogged main air bleed in a float-type carburetor on engine operation.

f) Check and adjust the float level of a float type carburetor.

g) The effect of an incorrectly adjusted float level on engine operation.

h) The effect of a worn or grooved needle valve and seat assembly in a float-type carburetor on engine operation.

i) The operating principles of a back-suction type mixture control.

j) The operating principles of an automatic mixture control.

k) The operating principles of economizer systems in float-type carburetors.

l) The effect of a ruptured diaphragm in a pressure-type carburetor on engine operation.

m) The basic function of a manual mixture control in an aircraft carburetor.

n) The location and operating of discharge nozzle used with pressure carburetor.

_____ School _____ Date

_____ Principal

A written examination required and practical projects.

1) Overhaul a float type carburetor.

2) Inspect and adjust the idle speed and mixture of a pressure carburetor.

3) Service and adjust various types of mixture controls.

3. Repair engine fuel metering system components (Level 2).

a) The operating principles of piston-type and single and double-diaphragm acceleration pumps.

b) The operating principles of direct fuel injection systems.

c) The purpose and operation of a venturi.

d) The function of a metering jet.

e) The purpose of an air bleed in a carburetor.

f) The purpose of an economizer valve in a carburetor.

g) Clean carburetor parts.

h) Repair a leaking float.

i) The adjustments that may be made on a pressure injection carburetor.

j) The effect of clogged impact tubes on engine operation.

k) The function of the synchronizer bar on fuel injection equipped engines.

l) The function and operation of the main and idling air bleed systems in a float-type carburetor.

A written examination required and practical projects.

1) Overhaul a float-type carburetor.

2) Perform a line maintenance inspection and adjustment to a pressure injection carburetor.

_____ School Date

_____ Principal

4. Inspect, check, service, trouble-shoot, and repair reciprocating and turbine engine fuel metering systems (Level 3).

   a) Adjust idling speed and mixture.

   b) The principles of operation of an automatic fuel control unit used on a turbojet engine.

   c) Trim turbojet engine fuel control system.

   d) The effect of increased altitude on engine fuel air mixture.

   e) The relative burning rates of various fuel air mixtures.

   f) The fuel-air mixture requirements of a reciprocating engine at various power settings.

   g) The operating characteristics of engines with direct cylinder fuel injection systems.

   h) Install, remove, and adjust direct cylinder fuel injection system components.

   i) The difference between a fuel injection system and a fuel injection carburetor.

   j) The cause of lean mixtures in a conventional carburetor system.

   k) The effect an inoperative vapor vent in a pressure-type carburetor has on engine operation.

   l) The factors that affect the density of the air entering the carburetor.

A written examination required and practical projects.

   1) Adjust idling speed and mixture.

   2) Adjust fuel control linkage for positive fuel cut-off and idle position on a fuel control unit.

_____ School _____ Date

_____ Principal

3) Install, remove, and adjust direct cylinder fuel injection system components.

4) Check, and service a vapor separator on a pressure injection carburetor.

G. ENGINE FUEL SYSTEMS (11th, 12th Year and RT)

1. Repair engine fuel system components (Level 2)

a) The types of engine-driven fuel pumps generally used with large reciprocating engines.

b) The purpose and operation of a fuel pump bypass valve.

c) The purpose and operation of fuel boost pumps.

A written examination is required and practical projects.

1) Remove, inspect, install and adjust an engine driven fuel pump.

2) Use fuel booster pump for starting engine.

2. Inspect, check, service, trouble-shoot, and repair engine fuel systems. (Level 3).

a) The causes of fuel pressure fluctation.

b) The characteristics of centrifugal-type fuel boost pumps.

c) The fuel system requirements for aircraft certificated in the "standard" classification.

d) The usual sources of aircraft fuel system contamination.

e) The purpose and requirements for strainers in fuel tank outlets.

School _____ Date _____

Principal _____

f) Inspect aircraft fuel tank sumps and fuel strainers.

g) Adjust engine-driven fuel pump output pressure.

h) The location and operation of main fuel strainers.

i) The causes and effects of fuel system vapor lock.

j) The location and operation of fuel valves.

A written examination is required and practical projects.

1) Ground operate and service a reciprocating engine.

2) During run-up preflight a reciprocating engine.

3) Adjust engine driven fuel pump output pressure.

4) Remove, clean and inspect the fuel sump and strainers.

H. INDUCTION SYSTEMS (11th, 12th Year and RT)

1. Inspect, check, troubleshoot, service, and repair engine ice and rain control systems (Level 2).

a) The principles of alcohol injection to control induction system icing.

b) The effect of ice within the induction system on engine operation.

c) The operating principles of carburetor air heaters used to prevent or eliminate ice in an engine induction system.

d) The method used to prevent the entry of rain into the induction system of a reciprocating engine.

e) The operating principles of electrically heated inlet ducts.

f) The use of engine bleed air to control engine inlet icing.

g) The causes of carburetor and induction system icing.

_____ School _____ Date

_____ Principal

A written examination is required and practical projects.

1) Install and adjust a carburetor heat system.

2) Remove, clean, inspect and install induction system screen.

2. Inspect, check, service, and repair heat exchangers and superchargers (Level 2).

a) The effect of using heated air during periods of high engine power output.

b) The pressures present in various portions of the induction system of supercharged and unsupercharged reciprocating engines.

c) The principles of operation and control of turbo superchargers.

d) The principles of operation and control of integral superchargers.

e) The purpose and operation of the induction system impeller used in some radial engines.

A written examination is required and practical projects.

1) During ground operation of an engine operate the carburetor heat valve.

2) Inspect the impeller of a radial engine.

3) Remove, clean, inspect and install an intake pipe.

3. Inspect, check, service, and repair carburetor air intake and induction manifolds (Level 3).

a) The position of the carburetor heat control during engine starting.

b) The purpose and location of the induction system screen in a reciprocating engine.

9697

_____ School _____ Date

_____ Principal

c) The purpose and location of the "hot spot" heater in the induction system of some reciprocating engines.

d) The installation and operation of a multi-point priming system on a radial engine.

e) The purpose, location, and servicing requirements for carburetor air filters.

f) The purpose and operation of RAM air intake ducts on reciprocating engines.

A written examination is required and practical projects.

1) Functionally test an engine.

2) Remove, clean and inspect carburetor air filters.

3) Fabricate and install a primer line.

4) Remove, clean and inspect the RAM air intake ducts.

I. ENGINE COOLING SYSTEMS (11th, 12th Year and RT)

1. Repair engine cooling system components (Level 2)

a) The attachment of cylinder head baffles.

b) The material used in the construction of air baffles.

c) Reprofile cylinder fins.

d) The effect of valve adjustment on the heat rejection rate of an engine.

A written examination is required and practical projects.

1) Remove and replace intercylinder baffles.

2) Remove and replace head baffles.

3) Repair a broken cylinder head fin.

_____ School _____ Date

_____ Principal

2. Inspect, check, troubleshoot, service, and repair engine cooling system (Level 3).

   a) The operating principles of the cooling system of vertically installed air-cooled helicopter engine.

   b) The effects of excessive heat in an aircraft engine.

   c) The purpose of fins on engine cylinders.

   d) The effect of incorrectly installed baffles on engine operation.

   e) The function and operation of cowl flaps.

   f) The effect of fuel-air ratio on engine cooling.

   g) The purpose and operation of cooling air augmenting systems.

   h) The principles of "pressure baffling" used in cooling aircraft engines.

   i) The precautions necessary during ground operation of aircraft engines.

A written examination is required and practical projects.

1) Remove, inspect and service cowl flaps.

2) Remove, inspect, service and install accessory cooling augmenting systems.

3) During ground operation of aircraft engines perform the following precautions

   (a) Fire Protection

   (b) Fuel Handling

   (c) Propeller Guards

   (d) Chocks and Brakes

   (e) Control of Engine Temperature with use of cowl flaps and wind direction

_____ School _____ Date

_____ Principal

J. ENGINE EXHAUST SYSTEMS (11th, 12th Year and RT)

1. Repair engine exhaust system components (Level 2)

a) The construction characteristics of exhaust augmenter tubes.

b) The materials used in exhaust system components.

c) The technique for cleaning ceramic coated exhaust pipes.

d) Detect and repair cracks in stainless steel exhaust pipes.

e) The methods used to compensate for the unequal expansion rate of exhaust system components.

A written examination is required and practical projects.

1) Remove, inspect, service and install exhaust augmenter tubes.

2) Remove, inspect and repair stainless steel exhaust pipes, both ball joint and straight types.

2. Inspect, check, troubleshoot, service, and repair exhaust systems (Level 3)

a) Inspect exhaust systems that utilize an exhaust heat exchanger.

b) The purpose and operating principles of the turbines driven by the exhaust gases of a turbo-compound engine.

c) The function and location of exhaust augmenters.

d) The cause and effect of "frozen" ball joints in an exhaust system.

e) Clean and test exhaust-type heating muffs.

f) The methods for torquing exhaust system clamps.

g) The purpose and construction of exhaust gas noise suppressors.

h) The effect of exhaust gas leakage on system components.

i) The purpose and operation of engine thrust reversers.

_____ School _____ Date

_____ Principal

A written examination is required and practical projects.

1) Clean and test exhaust-type heating muffs.

2) Remove, clean, inspect and install exhaust collector rings.

3) Inspect exhaust system that utilize an exhaust heat exchanger.

K. PROPELLERS (11th, 12th Year and RT)

1. Inspect, check, service, and repair propeller synchronizing and ice systems (Level 1)

a) The purpose of slinger rings on some propeller installations.

b) The method of preventing ice formation on propeller spinners.

c) The operating principles of electrical de-icing systems for propellers.

d) The purpose of the governor step motor in the synchronizing system.

e) The purpose of propeller synchronizing systems.

f) The operating principles of synchronizing systems.

g) The operating principles of fluid anti-icing systems.

A written examination only is required.

2. Identify and select propeller lubricants (Level 2).

a) The principal requirements for propeller lubricants.

b) The factors to be considered in selecting an oil or grease for a particular application.

A written examination is required and practical projects.

1) Remove counterweights, clean (consult manufacturer's maintenance manual for proper grease) lubricate install.

9701

School _____ Date _____

Principal _____

3. Balance propellers (Level 2).

   a) The effects of propeller unbalance on engine operation.

   b) Detect and correct vertical and horizontal unbalance in a two-blade propeller.

   c) Balance a two-blade propeller that uses a separate hub for mounting on the engine crankshaft.

   A written examination is required and practical projects.

   1) Balance a two-blade propeller that uses a separate hub for mounting on the engine crankshaft.

4. Repair propeller control system components (Level 2).

   a) Install oil control plugs in governors.

   b) Use manufacturer's data to repair components.

   c) The purpose and operation of a propeller governor.

   d) The forces acting on a governor to produce speed control.

   e) Determine the direction of rotation for which a propeller governor is set.

   A written examination is required and practical projects.

   1) Install oil control plugs in governor mock-up.

5. Inspect, check, service, and repair fixed pitch, constant-speed, and feathering propellers, and propeller governing systems (Level 3).

   a) The purpose and function of the parts of a propeller.

   b) The aerodynamic forces and loads acting on a rotating propeller blade.

_____ School _____ Date

_____ Principal

c) The operating principles of propeller controls used with turbine engines.

d) The meaning and significance of "static limits" as related to the installation of a fixed-pitch propeller.

e) The purpose of the metal tipping on a wood propeller.

f) Measure propeller blade angle.

g) The meaning of propeller blade "back" and "face."

h) The method of making changes in the speed and power output of an engine equipped with a constant-speed propeller.

i) The operation of the distributor valve assembly of a hydromatic propeller.

j) The normal position of a constant-speed propeller during take-off.

k) The effect on engine operation of changing propeller pitch settings before a steady oil pressure is obtained after engine starting.

l) The meaning and significance of "critical ranges" established for some engine-propeller combinations.

m) The operation of a propeller during the feathering cycle.

n) The operation of a propeller during the reversing cycle.

o) The purpose of placing a propeller in a specified position prior to stopping the engine.

p) The relationship between blade position, airspeed, and angle of attack of the propeller blades.

q) The operating principles of two-position and constant-speed counterweight propellers.

_____ School _____ Date

_____ Principal

r) The method of lubricating the pitch-changing mechanism of a hydromatic propeller.

s) The method of checking a steel propeller hub or blade for cracks.

t) The general procedure to be followed when using the chemical etching process to inspect aluminum alloy propeller blades.

u) Determine whether a bent aluminum alloy propeller blade can be repaired by cold straightening.

v) Clean and protect aluminum propeller blades.

w) The procedure for treating minor nicks and scratches on aluminum propeller blades.

x) Determine the blade pitch stop settings on a variable-pitch propeller.

y) The operating forces used to make blade pitch changes on various types of variable pitch propellers.

z) The location and purpose of propeller blade cuffs.

A written examination is required and practical projects.

1) Measure blade angle.

2) Place blades in high pitch and check condition of piston.

3) Remove nicks and scratches from the metal tip of a wood propeller.

4) Check the settings of the counterweights for maximum blade angle.

5) Remove the dome, inspect the pitch changing mechanism, lubricate, and install dome.

_____ School _____ Date

_____ Principal

6) During ground run-up operate propeller through complete range.

7) Magnaflux a steel propeller blade.

8) Using caustic soda, etch an aluminum propeller blade.

9) By reference to AC43.13-1 manual, determine if a blade of an aluminum propeller can be repaired.

6. Install, troubleshoot, and remove propellers (Level 3)

a) Perform an operational check of propeller feathering system.

b) Detect and correct front and rear cone bottoming of a propeller installed on a splined crankshaft.

c) The purpose and use of snap rings on propeller installations.

d) The purpose and use of propeller cones in some propeller installations.

e) Determine the amount of contact between a tapered crankshaft and the propeller hub.

f) Install and track a fixed-pitch and constant-speed propeller.

g) Detect and correct looseness in a cable-operated propeller control system.

h) The most likely indications of a damaged piston-to-dome seal in a hydromatic propeller.

i) The most likely cause of oil leakage around the rear cone of a hydromatic propeller.

_____ School _____ Date

_____ Principal

j) Perform an operational check of a propeller reversing system.

k) The constant-speed propeller setting used when checking ignition systems.

l) Adjust a propeller governor so that the propeller will operate within the correct range.

m) The purpose and significance of preloading the pitch-changing mechanism in a hydromatic propeller.

A written examination is required and practical projects.

1) Perform an operational check of propeller feathering system.

2) Remove a constant speed propeller, and check front and rear cones for proper seating.

3) Install and track a fixed pitch and constant-speed propeller.

4) Adjust governor control cable for proper stops and tension.

5) Remove hydromatic dome. Inspect condition of seal and replace dome.

_____ School _____ Date

_____ Principal

7. FACILITIES

POWERPLANT TECHNICIAN CURRICULUM

The following is a brief description of the powerplant facilities. Each shop is provided with sufficient working space and appropriate benches, part racks, etc. to enable each student to have unrestricted and uncrowded working conditions. Degreasing, washing and sandblasting equipment including air and water are provided. Sufficient engines, magnetos, starters, generators, carburetors, propellers, precision measuring tools, etc., are provided to enable each student to work under the proper student - equipment ratio. The powerplant equipment is complete enough to permit the actual overhaul of most powerplants and their accessories.

Suitable and separate space with either permanent, portable, or mobile test stands and test clubs for operating engines is provided.

All space, equipment, supplies, etc., exceed the amount required by the FAA.

Suitable storage facilities are available in each shop for tools, supplies, materials and equipment.

10TH YEAR POWERPLANT

_____ School _____ Date

_____ Principal

9. TEACHERS

There will be at least one teacher for 25 students in each shop or laboratory. The teachers of shop subjects will hold the appropriate mechanic certificates and ratings issued by the FAA.

Specialized teachers, who are not certificated mechanics, can be used to teach mathematics, science and mechanical drawing as called for in the new curriculums.

Traffic Accident Investigation Teaching Guide.

North Carolina State Board of Education, Raleigh. Law Enforcement Training.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - Apr69 73p.

DESCRIPTORS - *TEACHING GUIDES; *TRAFFIC ACCIDENTS; *TRAFFIC REGULATIONS; *TRAFFIC SAFETY; LAW ENFORCEMENT; *POLICE

ABSTRACT - Prepared by officers of a North Carolina police department, this teaching guide is written in outline form and provides information concerning traffic accident investigation. Chapters cover: (1) classifications and definition of accidents, (2) what an accident investigation involves, (3) causes and factors involved in accidents, (4) planning an investigation, (5) steps in conducting and reporting an investigation, (6) driver, pedestrian, road, weather, and vehicle conditions, (7) speed and skidmarks, (8) hit and run investigation, and (9) legal responsibilities. B. Testifying in Court
C. Common Court Situations
D. Appearance and Behavior in Court
E. Presenting Your Facts
F. Cross Examination

CHAPTER XVI

I. Assisting in Prosecution
A. Bringing Traffic Violators to Trial
B. Knowledge of Law
C. Assisting the Prosecutor
D. Adjudication and Penalization
E. Other Factors to Consider Which Effect Enforcement Productivity

9722

CHAPTER I

I. Classification and Definition

A. The traffic accident investigation is concerned chiefly with accidents which involve one or both of two elements: Motor vehicles and trafficways:

1. Trafficways: The entire width between boundary lines of every way or place of which any part is open to the use of the public for purposes of vehicular traffic as a matter of right or custom.

2. Roadway: That portion of a trafficway which is improved, designed or ordinarily used for vehicular travel.

3. Traffic Unit: Any person using a trafficway for travel, parking or other purpose as a pedestrian or driver, including any vehicle, other device, or animal which he is using.

a. Non-Contact Unit: A traffic unit which contributes to an accident, but strikes nothing and suffers neither damage or injury.

4. Motor Vehicle: Every device which is self-propelled and every vehicle which is propelled by electric power obtained from overhead trolley wires, but not operated upon rails.

5. Motor Vehicle Accident: Any event that results in unintended injury or property damage attributable directly or indirectly to the motion of a motor vehicle or its load.

a. Motor Vehicle Traffic Accident: Any motor vehicle accident occurring on a trafficway. (Automobiles or Collision on a Highway)

b. Motor Vehicle Non-Traffic Accident: Any motor vehicle accident which occurs entirely in any place other than a trafficway. (Private Property)

c. Non-Motor Vehicle Traffic Accident: Any accident occurring on a trafficway involving persons using the trafficway for transportation, but not involving a motor vehicle in motion. (Ex. Collision between pedestrian and bicyclist on a sidewalk)

d. Multi-Unit Traffic Accident: Traffic accident in which two or more traffic units are involved.

9723

NOTE: There must be property damage or personal injuries or there is no motor vehicle traffic accident, and it must be attributed to the motion of the vehicle.

II. Other Classifications of Accidents

A. Running off the road

1. Non-collision on the road

2. Collision on the road

III. Classification of Damage and Injury

A. Property damage

B. Personal injury

1. Non-visible

2. Minor visible

3. Serious visible

4. Fatal

a. Any death that occurs within twelve months of the motor vehicle accident.

9724

CHAPTER II

I. Accident Investigation, What It Is and Why It Is Important

A. Accidents are investigated for four main reasons:

1. Everyone involved is curious about causes and circumstances of the accident.

2. Police are also interested in finding out whether there is enough evidence of law violation in the accident to take enforcement action.

3. Claims attorneys and adjusters want to determine negligence on the part of the drivers involved in the accident so that claims can be properly adjusted.

4. Officers and others want specific information about accidents to know how to prevent them in the future.

B. Investigation enforcement results in citations or arrest by police, for law violations of any kind discovered in connection with the accident.

1. It may be for one of three different kinds of violations:

a. Violations which contributed to the accident such as failure to stop for a traffic signal.

b. Violations of other traffic laws discovered in the course of investigation but which did not contribute. (Ex. Driving without license.)

c. Violations not relating to traffic such as car theft or transporting narcotics.

C. Settlement of Claims

1. Perhaps half of all motor vehicle accidents involve possible claim settlements. A large percentage of these are settled out of court, but the remainder require some degree of investigation or study.

2. Police are nearly always in position to get the best first-hand information about the circumstances of a traffic accident.

3. Two good reasons why a police officer should gather accident information not needed by his department, so long as the equipment and time are available:

9725

a. Because it is important to the public, especially when an injured, ignorant, or confused person is unable to do it for himself.

b. Because an officer, when asked about it later, will appear incompetent if he has not made observations and measurements which he could easily have done.

D. Officials Who Want the Information:

1. The law makers would not know what laws to pass if they did not have sufficient information on why the accident happened.

2. Educators (drivers) would not know what to teach.

3. Engineers (road and car) would not know how to improve roads and traffic control devices.

4. Police administrators must have information on kinds of violations, times when violations are most likely to occur, and other circumstances of accidents. All this is necessary for intelligent planning of enforcement.

II. What Activities are Involved

A. Five kinds of activities are undertaken by traffic investigators:

1. Emergency measures to keep the accident from becoming worse, and to protect the scene from getting worse. This will be discussed in a later lesson.

2. Seeking facts

a. Ask questions

b. Listen to statements

c. Look at the results

d. Measure

e. Feel and smell

3. Recording information

a. Written

b. Sketch or diagram

c. Photograph

9726

4. Forming opinion about the accident

   a. Final step in accident investigation

   b. Most difficult part

   c. With facts you have

   d. Do not form opinions without facts to back you up.

5. Follow up

   a. Notify witnesses

   b. Cite or arrest

   c. Restore road conditions

   d. Testify

III. Reporting and Investigating Accidents

A. Accident reporting is getting and recording required information to establish exactly where and when the event took place, to identify who and what was involved, to describe how much injury or damage resulted.

1. Reporting tells what the overall accident situation is and whether it is getting better or worse.

2. It helps people who were injured and unable to do so at the time of an accident to find out who was involved.

3. It is used as a basis for directing traffic law enforcement and other safety activities.

B. Quality and Completeness

1. The accident report is the record of the accident used for official administrative purposes. Therefore, you should try to record all of the information required by the report form.

2. Identifying information

   a. This information should be exact because information relating to location of the accident is used in making spot maps.

   b. Information relating to drivers must be good enough so the licensing authorities may maintain accurate driver records.

9727

3. Activity cannot be considered investigation if it is merely:

   a. Receiving report, even required reports from one or more drivers.

   b. Taking information from drivers and recording it on official report forms.

   c. Securing additional information on names, addresses of drivers, owners, injured or witnesses.

   d. Visiting the scene only to give first aid, direct traffic, clear the roadway or obtain general information.

4. Complete investigation

   a. It is impossible. There can always be further refinement of data collection and analysis.

   b. No one expects you to find out all about any accident you work on. Yet, if you take the trouble to go to the scene of a traffic accident while people and vehicles involved are still there, you ought to be prepared to answer reasonable questions of fact about what you could have seen or heard.

IV. Accident Investigator

   A. Accident investigators are busy-bodies. They must be able to distinguish between circumstances connected with an accident and factors contributing to it. An intoxicated driver, for example, does not lead him automatically to conclude that intoxication contributed to the accident.

   B. Ability to testify

      1. If you go to the scene of an accident as an investigator, you can reasonably be expected to have some knowledge of the accident from your own observation and investigation. (Ex. An "Investigator" of an accident testified that there were skidmarks. When asked whether they were those of the front wheels, rear wheels, or both, he had to confess that he had not examined them closely enough to know.)

V. Legal Background for Police Traffic Accident Investigation

   A. Must have legal power to do certain things basic to the success of our traffic safety programs.

9728

1. Take charge at the scene. Usually there is a lot of confusion in connection with an accident. He must restore order, direct traffic.

2. Take enforcement action.

   a. Issue citations or make arrests, provided the evidence is sufficient to support such action.

3. Question witnesses and collect evidence. The police have the legal right to collect evidence pertaining to the condition of the driver or the vehicle, the wreckage, or clues at the scene.

9729

D. Trafficway condition

1. These attributes are such things as surface character, dimensions, traffic signals, controls and view obstructions, etc.

2. Modifiers are objects on the road. Road damages such as holes, ruts, wear and deterioration because of weather conditions.

II. Factors

A. Factors are any circumstances connected with a traffic accident. Without such, the accident could not have happened. These factors may be either actions or conditions. If a factor cannot, by itself, produce an accident, it should not be considered a cause. A true cause will produce the result. Therefore, cause is defined as a combination of factors and circumstances. Without either, the accident could not have occurred.

B. Operational factors: Operations which fail and lead to accidents are operational factors in those accidents.

1. Failure to obey traffic laws is a broad description of many but not all of the factors may be classified as operational.

2. Operational factors have been called "direct cause" of traffic accidents.

C. Contributing factors: Any circumstances connected with a traffic accident. Without such, the accident could not have occurred. These factors may be either actions or conditions.

D. Simultaneous factors

1. Factors which must be present at the same time to cause an accident.

2. Usually two are paired, such as road and driver. There could be more.

E. Speed as a "Cause of Accidents"

1. The rule of speed in traffic accidents is frequently debated. Without velocity, there would be no motion, and without motion, no accidents.

2. Adjusting speed is the most common strategy in driving. Speed is adjusted frequently.

3. Speed can put the driver beyond the point of no escape, at his point of perception.

9731

4. A safe speed is one adjusted to the potential or possible hazards of the road and traffic situation ahead.

5. Safe speed on a road is determined by the road rather than the particular driver or vehicle.

6. Safe speed is usually determined by such things as curves in the road and the marginal development along the road. Safe speed is affected by darkness, fog or smoke and slipperiness which is produced by water, snow or ice, etc.

F. Carelessness, negligence and recklessness

1. Carelessness is a breakdown of strategy or preparation and refers more often to decision than to recognition or performance.

   a. It can be an attribute of the individual. It is a general lack of alertness or vitality by which the traffic problem to be solved fails to get the attention it deserves.

2. Negligence - A more formal and legal way of expressing almost the same idea as carelessness. Negligence has become closely associated with law violation because law violations are generally prima facie negligence. Carelessness and negligence are about the same.

3. Recklessness - Having perceived a condition and not giving due caution and circumspection.

G. Law violations as causes of accidents

1. Many of us have been accustomed to thinking of law violations as causes of accidents. They are not. There are officially listed about 60 rules governing the behavior of vehicles and another 15 for pedestrians. These are written to decide exactly how people shall behave in using the highways so as to avoid accidents.

2. Violations of law in connection with an accident does not necessarily mean that the behavior or condition represented by the violation was a cause of the accident.

3. Driver intoxication is often a factor contributing to an accident. A driver may be guilty of driving while intoxicated without that circumstance being a contributing factor to his accident. (Ex. A drunk driver stopped at a light and is run into by a following car.)

9732

4. Failure to yield right of way cannot properly be considered more than a very far-fetched factor in an accident. Accidents involving failure to yield right of way permits us only to say that one traffic unit in a collision failed to take successful evasive action.

5. A vehicle, not being a person, cannot violate the law. It would, however, be possible to have vehicle behavior cause an accident against the will of the operator.

III. Traffic Accident Events

A. Chain of events

1. Hazard - Is a dynamic situation in which a crucial event will result if direction and acceleration of moving objects continued unchanged.

a. Perception and understanding of the hazard - perception of a hazard is seeing, feeling or hearing and understanding. The unusual or unexpected movement or condition could be taken as a sign of the accident about to happen.

b. Point of possible perception is the place and time at which the unusual or unexpected movement or condition could have been perceived by a normal person.

c. Maximum delay of perception occurs when the traffic unit does not sense a hazard until he hits it.

2. Encroachment

a. Moving into the path assigned to another traffic unit.

b. Crossing a barrier line or entering a crosswal when it is occupied.

c. Pedestrians can also encroach on a vehicle.

3. Start of evasive action - Is the first action taken by a traffic unit to escape from a collision course or otherwise avoid a hazard.

4. Leaving the roadway - moving off the roadway. That is the portion which is improved or designed or ordinarily used for vehicle traffic, excluding the shoulder.

5. Initial contact - The first accidental touching of an object collided with by a traffic unit in motion.

9733

6. Maximum engagement - Is the greatest collapse or overlap in a collision.

7. Disengagement - The separation of a traffic unit in motion from an object with which it has collided.

8. Stopping - Is coming to rest or stabilizing.

B. Key events

1. It determines the exact time, place and type of accident. It is wherever these three events occur first:

   a. Running off the road

   b. Non-collision on the road (overturning)

   c. Collision on the road

2. Repeated events - Sometimes occur in the same accident; for example, an accident may involve two or more collisions. (One striking fixed objects)

3. Results of an accident

   a. The damage to the vehicle and other property

   b. Injury to persons

   c. Marks on the road

   d. Final position of the vehicles or pedestrians

4. Study of results - Damage to cars often gives a clue as to what happened.

   a. The angle of collision can usually be determined.

   b. Some idea of the speed involved can be obtained.

   c. Results in terms of damage often effectively confirm or contradict the testimony of witnesses.

9734

CHAPTER IV

I. Preparation for Accident Investigation

A. Successful investigation takes special preparation

1. Investigating accidents is part of your job. It will pay you well to spend some time and effort in getting ready for this important activity.

a. The equipment is fairly easy to get ready. Not many things are necessary, but, like first aid equipment, they must be handy for use when you need them. (Forms, tapes, flares, jackets, crowbar, lights, etc.)

b. Training is necessary. You must have a clear idea of what you will have to do and how you are going to do it.

2. Know the general policies governing investigation.

a. What accidents to investigate. State statute states that an accident must be reported if damages are more than $100 or if there is an injury or fatality.

3. Objectives in investigation depend greatly upon departmental policy.

a. Knowing the necessary information that is required by your department and state

b. Extra duties that may arise in the investigation of an accident:

(1) Care for injury
(2) Fires or fire hazards
(3) Crowds
(4) Traffic

4. Habits - Have good habits in investigating accidents.

a. Be specific. Don't guess or estimate if you can measure.

b. Distinguish facts from opinions in what people tell you. Don't just have theories, conclusions or opinions.

c. See for yourself. Don't expect to learn all about the accident from what people tell you.

9735

d. Write information down at the time. Don't depend on memory. Write well enough so that you won't have to recopy later.

e. Grab at chances to get facts. Avoid the easy habit of thinking, "I'll get that later." Later is often too late.

5. Specific knowledge

a. Know your streets and highways. Know the short cuts to reach an accident scene quickly.

b. Maintenance of equipment. It is inexcusable for an investigator to be on a scene and not have the necessary equipment to make the investigation. It is poor public relations as well. So always check to see if you have beforehand all the necessary reports, pencils, tape measures, etc.

9736

CHAPTER V

I. Planning the Accident Investigation

NOTE: Many accident investigators wish many times they could go back and reinvestigate some accidents over. They failed to get some essential details. These and other mistakes usually result from a lack of planning.

A. Why planning is important

1. Definition of planning: Planning is laying out a course of action or method of accomplishing objectives.

a. This planning is necessary to accomplish the objectives.

b. The main objectives are to determine the cause, not to make a traffic arrest, only if there is a traffic violation.

2. In planning the investigation, officer must be guided by the objectives of the investigation. Any decision he makes should be based on attaining these objectives.

B. Principles of planning accident investigation

1. Flexibility is always necessary.

a. Too much organization can be just as harmful as disorganization.

b. Plan as far ahead as you can with the facts you have. Adjust and extend your plan as you work or as you receive more information.

2. Urgency is the basis of timing actions.

a.. Decisions based on urgency are intended to get things done first that you can least afford to put off.

b. Do the most important thing first, such as caring for injury, car catching on fire, or being hit by other cars, traffic and crowd control.

C. Six stages in accident planning

NOTE: Prepare yourself prior to learning of the accident. By that we mean all equipment such as tape, forms, lights and flares, etc.

9737

1. Upon learning of the accident, determine:

   a. Location of the accident. Know your area, reference to crowd, or if it happened on a busy street and need assistance.

   b. Type of accident. This is important due to types of vehicles such as gas trucks or other vehicles carrying inflammable material. This will probably be given to you by the dispatcher.

   c. Severity of accident. This means simply a fatality or severe injury or a possible fender-bender.

   d. Volume of traffic. If the highway is blocked - this goes right back to knowing your area.

   e. Need for assistance. You can have too much assistance at a small wreck.

   f. Division of work. If two men are answering the call, have one man in charge. Avoid having two officers testify on minor details of an accident. He can help you on skid-marks and testify with you.

   g. Where to park the patrol vehicle. Use it as a safety device and have the tools handy. (Any equipment which could be used in emergencies)

2. Upon arriving at the scene:

   a. Keep the accident from becoming more serious.

   b. Care for the injured.

   c. Handle fire hazards.

   d. Handle traffic hazards.

   e. Handle crowd control.

   NOTE: Handle the more serious first.

3. When emergencies have been handled:

   a. Start getting facts.

      (1) Get short-lived measurements and evidence.
      (2) Talk to witnesses fast before they leave.

   b. Locate drivers and witnesses.

9738

4. After getting short-lived evidence:

   a. Re-examine the scene.

   b. Determine causes of the accident.

5. After leaving the scene:

   a. Check injured parties at the hospital or doctor's office.

   b. Talk to witnesses at their home, office, etc. If possible, talk with them at the scene or as soon as possible thereafter.

6. Accident investigation follow-up: Prepare yourself for court. Be sure to have all the facts concerning the accident and the violation, if any. Do not base your decisions on opinions.

<u>NOTE</u>: Only move an injured person when the moving of this person would be less hazardous than leaving him at his present location. Avoid handling billfolds or ladies' handbags. Have a working agreement with the press on holding up publication in death or serious crimes until they check with you, especially on fatal injuries. The family must be notified.

9739

CHAPTER VI

I. Protecting the Accident Scene

A. Proceed to the accident scene quickly and safely.

1. Have sufficient information about the accident and drive accordingly.

a. Severity of traffic conditions may require more urgency on your part. Govern your driving according to the accident type.

2. Necessity to get there quickly but safely

a. To protect the scene from further accidents

b. To protect lives and render first aid

c. To protect the scene from possible theft

d. To protect and preserve physical evidence at the scene

B. Park your patrol car safely and properly.

1. Avoid creating congestion or destruction of evidence.

a. Do not park illegally if possible.

(1) It creates a hazard for other equipment on the scene.
(2) It encourages civilians to park the same way.
(3) It creates poor public relations which are very important.

2. Use of equipment in and on the patrol car

a. Use of equipment should help you determine where to park the patrol car. (Flares, first aid, tape, etc.)

C. Make the scene safe.

1. Evaluating and determining what to do about:

a. Personal injuries

b. Fire hazards

c. Traffic hazards

2. Fire prevention and control

9740

a. Fire under the hood

(1) Cut off the ignition.
(2) Cut off lights.
(3) Remove battery cables.

b. Use the fire extinguisher if available. If not, use sand or dirt or anything that can be used as a smothering agent.

c. The existence of leaking or spilled inflammables

(1) Keep the crowd away from the scene.
(2) May require movement of injured persons to a safer location.

D. Radioactive material requires special handling

1. Remove all injured persons and bystanders away from the scene as soon as possible.

2. Notify the nearest Atomic Energy Commission office or the State Highway Patrol which has a direct line to all monitoring. Give as much information on cargo and injured persons as possible.

3. Give information on wrecked vehicle such as trucks, trains and the exact location.

4. Advise them if there is a river nearby, the weather conditions and the nearest airport.

5. Clear the area of non-essential personnel of a distance not less than 1500 feet. Move them up wind if possible. In case of fire, try to avoid the smoke.

6. Do not attempt to move the vehicle until you are sure the cargo is not disturbed.

7. Arrange for heavy equipment to stand by the accident scene.

NOTE: The departmental policy is to move all personnel back 1500 feet and the department will contact State Highway Patrol.

E. Care for injured and their property

1. Evaluate the nature and extent of injuries.

a. Severe bleeding

b. Shock, pale looking, glaring eyes or semi-conscious

9741

c. Compound and simple fractures

d. Spinal and neck injuries

e. Asphyxiation or other toxic poison

2. Provide only immediate and temporary first aid. Do not play the role of a doctor.

3. Arrange for transportation by qualified persons.

F. Theft prevention - You are usually in command of activities at the accident scene and, therefore, responsible for protecting property from further damage or theft. Theft prevention is important but not the principal reason for your presence at the scene.

G. Police authority to remove vehicles

1. Police officer has the authority to move a vehicle involved in a traffic accident. He may move it to a safe place. He is also authorized to have it towed away by a towing service if the operator of the vehicle is incapacitated or when absent from the scene.

2. Decision to move the vehicles in emergencies

NOTE: Use your departmental policies on wrecker service.

9742

CHAPTER VII

I. Interviewing Driver and Witnesses

A. The most important sources of information are drivers and witnesses. As part of the investigation the police may question drivers and witnesses to get certain facts.

B. Police responsibility to obtain sufficient evidence to take enforcement action when necessary. Obtaining information for two reasons:

1. It adds to the total information obtained from all sources.

2. It can verify or disprove some opinions based on observations of physical evidence or statements made by other drivers and witnesses.

NOTE: Remember that obtaining statements from people is not a goal of accident investigation but a method.

C. Principles of getting information

1. Be objective

a. Overcome your feeling about a person's race or business. Avoid your dislike of foreigners or wise guys.

b. Attitude toward women drivers, interest in certain kinds of accidents, or other similar personal reactions can get in your way when you start to ask questions.

c. These feelings can easily show in the expression on your face and the manner of your speech.

d. The person whom you are addressing, more quickly and surely than you think, senses your feeling and responds accordingly.

e. Try to hide your feelings by being businesslike.

f. Keep yourself out of the situation. That is being objective.

2. Be positive

a. The way you approach the person to be questioned determines to a large degree how successful you will be.

9743

b. Let the drivers or witnesses know that you are aware that they have some information and that you intend to get it. Never be reluctant to ask questions but ask them in a straight-forward, clear manner.

3. Be specific

   a. To get useful answers, be certain that the driver or witness understands your questions.

   b. Make them as specific and clear as you would like the answers to be.

   c. Be sure you know what the answer really means.

4. Don't suggest answers - you must not thrust your own opinions on those you are questioning.

5. Avoid conflict

   a. Try to avoid conflict between drivers and witnesses.

   b. To keep yourself out of conflict, be objective.

6. Be adaptable

   a. Don't settle into a routine.

   b. Avoid asking a set list of questions.

   c. Adjust questions to the person.

7. Verify statements

   a. By comparing statements

   b. By physical evidence at the scene

8. Be especially careful to verify the driver's identity and ownership of the vehicle.

9. Be diplomatic and understanding.

10. Do not embarrass people.

II. Driver

A. Locating drivers is the first thing to do after handling emergency conditions at the scene.

   1. What influences driver in answering questions:

9744

a. People are affected by various physical and emotional factors which influence their ability to give accurate information.

b. The mere fact of a police officer asking questions is often enough to create tension or even fear. Most people cannot think and talk as well as usual when they are upset or injured.

c. Signs of emotional stress are usually present. Heavy breathing, trembling hands, stuttering or thick-tongued speech, fumbling with the hands and inability to follow a discussion. Some people may be this way all the time and others may not show signs of being nervous.

B. Personal problems

1. The driver's ability or willingness to answer questions accurately is influenced by what he considers to be very important personal problems which may have little or no bearing on the accident.

C. Rationalization

1. Few people like to admit having done something wrong. It always tends to be "the other person's fault." Many drivers will figure out logical reasons for behaving as they did.

2. It is a very convenient way to escape self-condemnation and feelings of guilt or remorse.

3. It is a normal human process but a process that seriously affects the ability of people to be truthful and objective.

D. Shock amnesia is the loss or impairment of memory due to shock.

1. Results from shock due to serious injuries, severe loss of blood and other conditions.

2. The period of unconsciousness after the accident will usually be the same as the blank period before the accident.

E. Evading responsibility

1. Some people will deliberately try to mislead you by giving inaccurate information to avoid punishment, small fines or to collect damages.

9745

2. Some people simply will not admit mistakes. If you detect a flaw in a story even if it seems unimportant, check the rest of the story carefully. It may be entirely inaccurate.

F. Failure to observe

1. Many people cannot give good information simply because they failed to observe or they see what interests them.

2. Check what they tell you by their position and time of accident.

G. When and where to question

1. Conditions at the scene

2. Emergency first

3. Collect physical evidence that might be removed.

4. Condition of drivers or witnesses

5. Question driver as soon as possible.

H. What information to seek from drivers, two kinds:

1. One kind of information is necessary for making routine accident reports.

2. The other is essential in discovering what happened and who was at fault.

NOTE: Getting the facts on how and why, the ability to think up the questions to ask. Ask them so as to get the best answers. This is one of the things which make the difference between investigation and a mere report.

III. Identification of driver and vehicle

A. Before asking for any other information, check driver's license and registration card. (He is required by law to show this to any police officer.) Do not handle wallet, purse or other papers unless absolutely necessary.

B. Sometimes a passenger will falsely claim to have been the driver because the actual driver may have been intoxicated, under age, or had a bad driving record. Check witness as to who was driving.

C. Events of accident

1. Exactly where were you when you first saw the car?

9746

2. What were you doing at the moment you first saw the other car?

   a. Movement

      (1) Speed
      (2) Direction
      (3) Slowing down
      (4) Speeding up

   b. Attention

      (1) Where had you been looking?
      (2) Had you been talking to anyone?
      (3) Where were you when you first realized you were in trouble? (Point of perception)
      (4) What were you doing at the moment you realized you were in trouble?
      (5) Exactly what did you do, if anything, to avoid the accident? (Evasive action)
      (6) Then what happened? (Let the driver describe the actual key event.)
      (7) Exactly where did the collision take place? (Do not ask if you know the answer from your own observations of physical evidence.)
      (8) Where did you stop after the collision? (Do not ask if you already know the answer with certainty.)
      (9) What is the first thing you remember after the accident?
      (10) If driver was unconscious, ask what is the last thing you remember clearly before the accident?
      (11) Who did you first see after the accident? (This may give a good clue to a witness.)
      (12) What did you say to him? (Object: to get an idea of what explanation of the accident the driver gave right afterward.)

IV. Witnesses

   A. Importance

      1. Vital in determining what happened in many cases

      2. Of value even if they did not see the accident happen

      3. Courts inclined to give particular attention to statement of impartial witnesses

9747

B. How to locate witnesses

1. With diplomacy they can be located even though people generally are reluctant to get involved.

2. Look for the gabby individuals. Persons talking and waving hands may lead you to important witnesses.

3. Watch for signs and statements that indicate that the person saw the accident.

4. Circulate quietly, not with a chip on your shoulder.

5. Don't ignore children.

6. Take license numbers of cars parked nearby.

7. Take license numbers of cars passing toward you from the scene, particularly if there is no one at the scene.

8. Try to locate the first person to reach the scene.

9. Usually best witnesses are bystanders who had nothing to do with the accident.

C. Handle witnesses properly when found.

1. Approach confidently if fairly certain person knows something about the accident.

2. Treat people decently. Never scold or bully.

3. Be patient with confused or mentally-low types.

4. Avoid use of expression "witness." Use "Tell me what you saw."

5. Request rather than order.

6. Use statement rather than question form. Use "What did you see?" not "Did you see it?"

D. Seek valid and reliable testimony.

1. Persons riding in involved cars usually side with their driver but may make good witnesses.

2. Be alert to detect friend who poses as a disinterested observer.

3. Watch out for imaginative person who fabricates, gives excessive variation of degrees of speed, size, color, etc.

9748

4. Some persons have a desire to be important.

5. Some have special prejudices, dislikes, etc., which color their interpretations.

6. Some cite opinions as though they were facts.

E. Written statement

1. Provides opportunity to cross examine later

2. May result in hesitancy of witness to change his story later

3. Need not be elaborate in form, but should contain essentials such as

a. Where was he standing?

b. What was he doing in vicinity?

c. What he can testify to

d. Name

e. Age

4. Write the statement for the witness if he will not write it for himself.

5. Use positive statement "Sign here." Don't appear resentful if witness will not sign.

V. Passengers

A. Be sure to question all passengers involved, especially in a serious or complicated accident.

B. Find out relationship of each passenger to the driver. (Help to determine if he will be biased)

C. Try to question each separately and then compare stories.

D. Ask seating positions to determine if he was able to see and what he was doing at the time of the accident.

9749

CHAPTER VIII

I. Driver and Pedestrian Condition

A. In general, the same personal conditions that make drivers have accidents also make pedestrians have accidents. Whether it is a pedestrian or a vehicle with its driver, it is called a traffic unit.

1. Behavior is what the driver or pedestrian does.

a. Behavior of the person is reflected in part by the behavior of the traffic unit.

b. In investigating an accident, we must try to discover driver or pedestrian's condition that produces behavior as well as discover the behavior itself.

2. Driver or pedestrian conditions

a. A single road or vehicle condition can sometimes cause an accident, but far more often, faulty driver conditions by themselves result in behavior that causes accidents.

b. Some driver conditions almost always contribute to an accident as a factor.

3. Personality in driver

a. It may be considered as all the qualities which can explain individual behavior.

b. We are particularly concerned with personality traits and qualities which set one person apart from another.

c. There are three aspects of personality related to traffic accidents.

(1) Natural mental and physical abilities
(2) Learn abilities and knowledge which the person has acquired by study and practice.
(3) Motives and attitudes which determine how and why a person thinks and feels about things

d. Personality is affected by many temporary driver conditions such as

(1) Intoxication
(2) Fatigue
(3) Medicine

9750

(4) Illness
(5) These may influence nearly every aspect of personality related to driving.

4. Distinguish factors from circumstances

   a. Ask yourself: Would the accident have happened if this condition had not been present?

   b. A driver may have some dangerous impairment and yet that condition may not have had anything to do with the accident.

5. Distinguish between driver conditions before and after an accident. We are interested primarily in prior conditions as possible factors.

   a. Ask youself "Did this driver condition contribute to this accident or did the accident create the condition?"

   b. Not only may driver conditions suggest why an accident happened, but clues from the accident may suggest the driver condition contributing to it. (Ex. Open whiskey bottle in car may indicate the possibility of intoxication and vomit in or on the car may indicate sickness.)

6. Expert help is sometimes needed

   a. Unfavorable road conditions are usually easy to see during investigation but

   b. Vehicle conditions are more difficult to detect.

   c. Driver conditions, especially attitudes and emotions, are most difficult of all to discover.

      (1) Sometimes certain experts can help determine what driver conditions might have contributed.
         (a) Doctors can discover conditions like heart ailments.
         (b) Psychologists can explain personality factors which may be involved.
      (2) Your job is to make such observations as you can of driver conditions and inquire concerning circumstances which might suggest or preclude certain possible conditions. Ask an expert for help if you need it.

9751

141 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

7. When police have proof of a driver's condition

   a. Take what action is appropriate regardless of whether the condition contributes to the accident.

   b. Arrest for operating intoxicated is the most common police action.

   c. Certain driver conditions are hazardous but not illegal. For such conditions, enforcement action is difficult. (Ex. Falling asleep or a heart attack while driving is very dangerous but, in most locations, does not break a specific law. If the driver could have anticipated them, a general charge of reckless operation could be made.)

   d. No one is expected to inquire into all driver conditions mentioned here in connection with every accident. It would be impossible. Only the most serious receive careful study.

   e. If you think a driver's condition is serious, such as the driver being an epileptic, and he has several unexplainable accidents, you should refer the case to a licensing official for further study.

8. Natural abilities

   a. Deficiency in natural abilities can contribute to accidents in several ways. We are speaking of relatively permanent conditions, not diseases.

   b. Some physical or mental defects or deficiencies with which the person may have been born. These deficiencies are in these three areas:

      (1) Sensory conditions, seeing and hearing, becoming aware of road or traffic conditions
      (2) Conditions of mind and nerves, understanding hazardous conditions and making proper decisions
      (3) Bone and muscle conditions, the prevention of the operation of the controls on the vehicle

   c. Vision - There are a dozen or more eye conditions that can handicap a driver.

      (1) Visual acuity or sharpness of seeing at a distance, such as road signs. This deficiency is usually correctable with glasses.

9752

141

(2) Night blindness is the inability to see objects of low contrast in low illumination, such as a pedestrian in dark clothing against a dark background 200 feet away. With low beam headlights, wearing sun glasses is bad. It cuts down vision.

(3) Glare blindness slows recovery from viewing dazzling lights at night. This is common with older people. (Ex. A person complains about being blinded by the headlights and runs off the road.)

(4) Narrow field of vision is the inability to see toward the sides. When the field is very narrow, it is called tunnel vision. It cannot be corrected with glasses. (Ex. People with one eye, sometimes car windows that are fogged by moisture or frost gives the effect of narrow field of vision.)
NOTE: Average is 160°. Some people have 180°.

(5) Depth perception is the ability to judge distance of nearby objects with both eyes. Lack of depth perception, using two eyes, cannot be corrected by glasses. People with one eye lack this ability but are able to judge distance by other means. This takes special equipment to determine depth perception.

(6) Color blindness is the inability to distinguish certain shades of red or green. Color blindness is probably not very important in accidents. It is not a common condition. More males are color blind. Rarely do you ever hear of a woman being color blind. This is sometimes suspected when a person swears that he had the green light when it was red, not the fact that he is being dishonest.

d. Hearing defects do not often contribute to accidents. You might suspect it when they failed to hear a horn or train whistle or even while you are talking to them. They are having trouble hearing you.
NOTE: If your windows are closed, radio on and air conditioner, etc. has same effect.

e. Very short drivers and those lacking limbs may have difficulty making the car do what they want it to.

9753

(1) Such deficiencies contribute to accidents in cases where high manipulative skill such as turning movements are necessary.
NOTE: May have restricted license.
(2) Vehicles have special equipment to handle handicapped persons and they have special training. Most of the time they can compensate for them.
(3) Such conditions may contribute when you notice the driver or pedestrian having such deficiencies.
(4) Over weight, low strength, stiff or painful joints all contribute to the accident.

NOTE: Licensed driver examiners have the authority to re-examine any licensed driver as to whether he may retain his license.

f. Personality

(1) Personality includes all the human traits or characteristics which explain behavior, physical and mental abilities, knowledge, skill, motives and attitudes.
(2) Motives and attitudes are useful in explaining personal causes of accidents.
(3) The fact that some people do not drive safely, though they have the ability and knowledge, is what necessitates traffic law enforcement.

g. Punishment or threat has little effect on persons who do not know what is expected of them or on their ability to drive as required.

(1) It may also stimulate the driver to learn about those things which cause him to be punished.
(2) The more legitimate role of punishment is for those drivers who know what should be done and yet intentionally do otherwise.

9. Motive

a. Motive is a psychological concept used to explain "why" behavior occurs.

b. In traffic accidents we are concerned with explaining why a driver behaved in a certain way. (Ex. Too much to drink. Why is he angry?)

9754

10. Attitudes may be defined as more or less parmanent ways of thinking and feeling about things.

    a. Attitudes are useful in explaining why drivers behave the way they do.

    b. Attitudes may be good or bad for driving, depending on whether they are in line with safe practices. There are several specific attitudes and motives that frequently account for unsafe driving:

        (1) Showing off - driving reckless, etc.
        (2) Inferiority - being inconsiderate with their driving
        (3) Risk taking - racing, playing chicken, etc. This demonstrates their "real men" effect.

11. Emotion

    a. Further concept which is useful for understanding driver behavior

    b. Emotions refers to the way we feel about something. There are many different kinds of emotions that can affect driving:

        (1) Anger - leads to reckless, aggressive behavior
        (2) Fear - causes hit and run driver to evade responsibility
        NOTE: Emotions, like the other psychological aspects of personality, are often difficult to relate to an accident.
        (3) Most all drivers are emotional after an accident, which is normal.
        NOTE: In attempting to investigate the emotions in an accident, inquire as to the events leading up to the accident and how the driver felt about them.

B. Reaction time

    1. This is the time after full perception of a situation that a person takes to decide what to do about it and start acting.
       NOTE: The average time is about 3/4 of a second.

    2. There are four kinds of reactions that are recognized, based on the amount of thinking necessary. The less thinking, the shorter the reaction.

        a. Reflex reactions

        b. Simple reactions

9755

c. Complex reactions

d. Discriminative reaction - less dangerous of possible action

3. Reaction time is affected by many things such as

a. Age

b. Strength of stimulus

c. Physical conditions

d. Habits

NOTE: Reaction is not a separate characteristic by itself. It depends on physical and mental conditions, knowledge, skill and attitude. Thus, reaction time includes the time required to comprehend the situation after it has been seen or heard.

4. Perception time

a. Is the interval between the moment when a movement or condition could have been perceived under normal conditions and actual perception

b. There must be perception before reaction is possible.

c. Perception time, as used here, includes time required to comprehend, understand or evaluate. (Ex. A person may be looking directly toward an object but may take some time to recognize it.)

5. Distractions

a. Something heard, felt or touched

b. Something that diverts or turns the mind and eyes away from something that close attention should be paid to

c. Distractions caused by minor emergencies and annoyances

(1) Demands from inside the vehicle
(2) Demands from the driver himself
(3) Distractions from outside the vehicle such as boy looking at girls

9756

(4) Preoccupation, day dreaming, any emotional thought. Anyone can be distracted, but you rarely can say positively that distraction was a factor because there usually is no permanent evidence of it.

d. Often distractions can be discovered by asking

(1) What were you doing just before the accident?

(2) What were you thinking about just prior to seeing you were in trouble? You must consider distractions as a possibility when there is a long perception time.

C. Poison, medicine, fatigue and illness

1. Effect - Various chemicals taken into the body, many diseases, and fatigue have some effect on most parts of personality that are important to safe driving.

a. Alcohol - It affects emotions and superficial attitudes more than anything else. There are many degrees of intoxication which affect a driver's ability to solve problems of the road and traffic and control his normal mental or physical faculty.

NOTE: Do not attribute all unusual actions on alcohol, as there are many other pathological reasons that give alcoholic symptoms.

b. Narcotics can seriously affect the driver's ability to drive safely, much the same effect as alcohol.

(1) Other drugs - stimulant drugs (Bennies, pep pills, etc.)

c. Carbon monoxide has, in the early stages, symptoms of alcohol, fatigue, etc.

d. Fatigue can produce almost every outward symptom of intoxication.

e. Illness - Do not confuse alcohol, drugs and medicine with illness such as heart, epilepsy, diabetes, shock or mental illness.

D. Legal requirements for drivers

1. This includes licensing.

2. In connection with investigation of accidents, you have an opportunity easily to discover if the driver has met the necessary legal requirements.

   a. Driving while under age

   b. Examine a license closely to determine whether it is valid.

   c. Examine the license for restrictions.

9758

CHAPTER IX

I. Road and Weather Conditions

A. Combination of causes

1. Road conditions

a. Definition: Includes roadway, trafficways and anything off the highway that might contribute to an accident

b. Unfavorable road driving, weather conditions at the time of the accident, are not always factors of the accident.

c. Road and weather conditions are only causes when they contribute to the accident.

d. Ask yourself if the accident would have happened if the conditions had been absent.

2. View obstructions

a. Horizontal

(1) Full
(a) Vehicle in the roadway
(b) Building
(c) Trees, shrubs
(d) Billboards, lighting
(2) Partial: can result in hasty glances

b. Vertical (Time, distance, relation)

(1) Such things as hillcrests and bridges

3. Reduced visibility

a. Darkness

b. Fog and smoke, dust storms

c. Rain and snow

d. Glare

(1) Headlights
(2) Back lighting and fixed lighting
(3) Sun

4. Surface conditions

a. Type of road surface

9759

(1) Slipperiness
(2) Wet
(3) Ice

b. Road surface material

(1) Concrete
(2) Asphalt
(3) Brick

c. Characteristics of roads

(1) Intersections - The different angles or sudden turns, an offset that you may encounter
(2) Width of road - The sudden narrowing, causing sudden changes in speed, likely to cause rear end accidents
(3) Alignment - The level and straight alignment of the roads. The angle of the roads. The failure of traffic engineers to properly warn drivers, by signs, of unusual alignment problems such as curves, etc., is a factor.

d. Constructions and faults

(1) Ruts
(2) Holes in the road
(3) Curbs
(4) Lips or drop offs
(5) Shoulders - types and condition, sandy, dirt or grass

e. Traffic control devices

(1) Types of devices
(a) Signs
(b) Signals
(c) Markings
(2) Conditions
(a) Visibility
(b) Operating
(c) Devices missing
(d) Devices not operating
(e) Decreased visibility
(f) Sign wording too small
(g) Driver's view of sign obscured

B. What to look for on the road after an accident

1. Debris

a. Accumulation of broken parts of vehicle, rubbish, dust or dirt and other materials left at the accident scene by the accident vehicles

9760

b. Underbody debris is debris that comes from beneath the car. May reveal:

(1) Location of key event
(2) Path vehicle followed after impact
(3) Direction of force
(4) Identification of vehicle
(5) Distance vehicle traveled after initial impact

c. Vehicle parts

d. Vehicle fluids

2. Damage to roadside objects (fixed objects, trees, posts, houses, etc.)

a. Path vehicle took after impact

b. May reveal the part of vehicle doing the damages

c. Sometimes it may determine the speed of the vehicle.

3. Imprints - any marks on the pavement or ground that are left without the sliding of tires or rotating wheels

4. Skidmarks

a. Tire marks left on the road by tires that are not free to rotate

b. Kind of skidmarks

(1) Pavement grinding, stone, gravel or grass
(2) Tire grinding on the pavement
(3) Smear of soft materials, snow or mud
(4) Smear of bituminous materials (tar and asphalt)
(5) Tire smears, melting of tires on road
(6) Furrow, the plowed depression made by sliding tire material piled up on each side and usually at the end
(7) Erasing or wiping of the pavement
(8) Squeegee marks or wiping of moisture from the pavement

5. Scuff marks - signs left on the road by tires that are sliding sideways, etc.

6. Scratches

a. Marks left on a road by sliding parts of vehicle other than tires

9761

b. There are two types

(1) Slight tearing
(2) Rubbing off of vehicle material

7. Gouges

a. Holes or grooves when material is dug out of the pavement by parts of the vehicle

b. There are three types

(1) Chip gouges
(2) Chop gouges
(3) Groove gouges

9762

CHAPTER X

I. Vehicle Conditions

A. Reasons for suspecting vehicle conditions contributing to the accident

1. When you find there is no evidence of the driver or road at fault, then it is safe to believe the vehicle is at fault.

2. Damaged or defective parts

3. Circumstances surrounding the accident

4. Great age of the vehicle (bad condition)

5. Size, weight and shape of load carried on the vehicle

6. Claims or statements of drivers and witnesses may cause you to suspect trouble with vehicle

7. Marks on the pavement prior to the key event (gouge, scratches or marks)

B. Parts of the vehicle likely to contribute to accident

1. Tires

2. Wheel suspension

3. Steering gear

4. Brakes

5. Engine and transmission

6. Accelerator sticking

7. Body of vehicle

8. Windshield and rear windows

9. Headlights

10. Tail lights

11. Miscellaneous equipment, horn, wipers, rear view mirror, etc.

II. Vehicle Damage and Conditions

A. What to look for

9763

1. It can tell how the accident happened.

2. It can tell why the accident happened.

B. Kinds of damage and defects

1. Preceding but not contributing to

2. Preceding and contributing to

3. Damage brought about during collision

4. Damage after collision and before final position

5. Damage brought about at the scene but following the accident (Ex. The wrecker causes damages.)

III. What the Vehicle Shows About How the Accident Happened

A. Body of car (bumpers, glass, doors, etc.) and what it may show

1. It will or may show the direction of travel and the extent of maximum engagement.

2. Suggestions for examination - study the damaged parts to find out which way they were pushed.

3. Examine the car for paint from other vehicles.

4. In pedestrian accidents, examine the damaged parts to determine the parts of pedestrian's clothes or body. (buttons, blood, flesh, hair, etc.)

B. Interior of the car

1. May show where each occupant was sitting prior to the accident

2. May show the direction from which the force came and who was driving

C. Tires

1. If the tire is cut or blown out, it can indicate the direction of force.

2. Also indicates movement of car before, after and during the collision

D. Gear position (especially trucks) - May give a clue to the possible speed of vehicle

E. Speedometer - May show the speed of vehicle at time of collision if it is in frozen position. (Variable factors influence position)

9764

F. Problems of investigation

1. Determine if driver imagined vehicle failed or if it really did.

2. Determine whether the broken part caused the accident or if the accident caused the broken part. (Check driver's statement against the broken parts)

3. Determine if the vehicle had continuing defects. (Brake lights or headlights, etc.)

G. Illegal condition discovered in accident investigation- When police discover an illegal condition of the vehicle in connection with an accident, whether the condition contributed to the accident or not, they should take appropriate law enforcement action.

9765

CHAPTER XI

I. Speed and Skidmarks

A. Introduction

Normal skids are those which occur on a flat, level surface of uniform slipperiness when all wheels are locked within perhaps a quarter of a second after brakes are applied. All wheels have tires of approximately the same kind.

1. Common errors in considering skidmarks

a. Courts are not informed on the evidence of skidmarks and not willing to accept them.

(1) Too complicated
(2) Too many variables such as size of tires, types of vehicles, etc.
(3) Never heard of speed formula

b. Skidmarks are misinterpreted.

2. Skidmarks occur when the following takes place:

a. Wheels slow down and begin to slide.

b. Locked wheels continue to slide, causing the following:

(1) It causes a grinding effect or causes the rubber to melt from the heat that is generated. Surface material may be displayed. This brings about a scraping or plowing effect.

NOTE: Temperature wise, surface tar will melt at 300° F., rubber at 600° F.

3. Skidmarks may show or indicate the following:

a. Position of car on roadway

b. Point of impact

c. It can also indicate the action of the drivers.

d. It can indicate the minimum speed the car was traveling.

B. Factors influencing skid distance

1. Speed (this is the principal factor)

9766

2. Pavement surface

   a. Slippery surface makes for longer slides.

   b. A number known as coefficient of friction describes the road surface or drag factor of the pavement.
      NOTE: Drag factor is the amount of drag that a pavement puts on a tire or tires on a wheel compared to the weight on that wheel. It is expressed by a number, usually a decimal fraction. (Ex. If a wheel presses down on the road with a force of 1000 lbs. and the road produces a horizontal force or drag on that wheel of 500 lbs., the drag factor is 500 divided by 1000 which equals 0.50. Ice can be 0.10 or very slick, while other surfaces may be as high as 1.20, which is very rough.

3. Grade or slope - Rise or fall in feet per 100 ft. plus or minus 5%.

   a. On a grade, less skid

   b. On a slope, more skid

C. Other factors having small effect

   1. Tires - All rubber tires are about equal in stopping resistance.

      a. Normal size tires have no effect. Air pressure has some but not much. You measure dual wheels as one.

      b. The weight of the vehicle will cancel itself out.

      c. Wind velocity makes no noticeable difference.

      d. Temperature of the air and pavement
         NOTE: Temperature of the air and road surface make some difference. In general, on ordinary pavements, hot weather produces longer stopping distance.

      e. The direction of the slide (backward, forward, etc.) will make some difference but not a noticeable amount

D. Identification and measurement of skidmarks

   1. Each wheel which skidded must be:

a. Measured separate as to length and position on roadway

b. Each wheel must be recorded properly on your field sketch or notes.

2. Beginning point - is critical and not always obvious

a. The shadow marks are important if you can identify them. You can see the shadow marks by looking low along the line of the skidmark.

b. Overlapping - When overlapping occurs, sometimes the beginning point must be assumed. The end of the rear wheel slides and the beginning of the front are obscured by the overlapping. If you look carefully, you can usually find the place where the rear wheel stopped. It is on top and usually a little off the side.

c. Identify the front and rear wheel skidmarks.

(1) Front wheels are normally indicated by dark smears on the outer edge of each.
(2) Rear wheel skidmarks are normally identified by a solid black smear.
(3) The ending point of a skidmark is usually clear and definite - ends abruptly.

3. Interruptions

a. Gaps are the distance between the releasing and reapplication of the brakes. You must include in your measurements, when you finish, deduct the total feet of gap. The gap is usually 10 ft. or more.

b. Skips are caused by bouncing or bumping over ruts, rails or holes in the road. Include the skips as part of the skid. They will usually run one (1) to three (3) feet.

4. Identification of skidmarks with the vehicle that made them

a. Witnesses and drivers

b. Skidmarks leading up to a certain car

c. If you have fresh marks and have probable cause, compare them with tires at the scene.

d. Photographs

9768

5. Road surface

   a. Composition of road surface should be recorded fully on accident reports. (Types of surface)

   b. Wet, dry or slipperiness

E. The drag factor or coefficient of friction is described as follows:

1. Description of road surface alone is not adequate to give drag factor.

   a. It can be estimated by experts. (Drag factor) However, there still is a margin for error.

   b. It may be the best you can do in some cases such as ice or wet roads.

2. Test skids are the "Best method for establishing the drag factor."

   a. The accident car is preferred if it is driveable, or a car as near like it as possible.

   b. The car should be driven at a predetermined speed, preferably 25 to 40 m.p.h.

   c. Note the m.p.h. you are driving. Apply your brakes hard and hold until car comes to a stop.

   d. Skidmarks are then measured carefully and recorded.

      (1) Add all four wheels together.
      (2) Divide by four (4) for your average length.

3. Formula for coefficient of friction: F minus or plus F equals 0.033 S2/d or F equals $\frac{S2}{30d}$

9769

CHAPTER XII

I. Hit and Run Investigation

A. Differences between hit and run and other accidents

1. Accident information is a fact finding operation with everyone accounted for.

a. Hit and run requires finding the driver evading responsibility.

b. Elements of the violation

(1) Prove who was driving at the time of the accident.
(2) Knowing that they were involved in an accident
(3) Left without satisfying legal obligations
(4) Make inquiries as soon as possible after a hit and run for description and investigation.

c. Importance of a hit and run investigation

(1) Criminal aspect
(2) The effects of public opinions
(3) The danger to the police officer

B. Directing the hit and run investigation at the scene

1. Determine if it is a hit and run - if drivers are not all there, find out where they are.

2. Guide for the investigating officers to follow:

a. Get the situation under control.

b. Obtain all the information you possibly can that relates to the identification of the hit and run vehicle and the other parts of the vehicle.

c. Transfer this information to the dispatcher to be put out to all units.

d. Search and collect evidence and preserve it.

e. Call for expert help if needed.

3. Standard operating procedures:

9770

a. Broadcast a description of the hit and run vehicle with information on vehicle, direction of travel, etc.

b. Dispatch special investigators, if possible.

c. Direct road blocks.

d. Check local files.

C. Clues useful in hit and run investigation

1. Reason for trying to find clues:

a. Show what kind of vehicle was involved in the accident.

b. Identify the particular vehicle when found as being in the accident.

c. Identify the person as the driver of the vehicle.

d. Verify or disprove the statement of other drivers and witnesses or theories as to what happened.

2. The material or evidence you discover at the scene very often will lead your investigation step by step to other evidence or conclusions of the greatest value.

3. Gathering materials for scientific examination

a. You may not be able to figure out the meaning of certain materials found at the scene.

b. You must preserve such materials for possible scientific examination.

c. When in doubt as to the connection, save all possible clues. It is much better to save materials found at the scene than to regret later that you didn't.

d. Any materials found at the scene which can't be explained at the moment as having any bearing on the investigation at hand shall be considered as physical evidence until the connection can be determined.

e. Actually what you are doing is substituting facts for guesses to find out who, what and why.

D. What to look for

1. Debris

   a. The accumulation of broken parts of vehicles, rubbish, dust and other materials left at the accident scene by a collision

   b. Debris samples can be collected and preserved but matched and analyzed by an expert to identify the vehicle or place it came from.

2. Parts of vehicles are the most important debris in a hit and run accident. When you match broken edges with parts still on the car they are positive identification. Even when they don't match, they may be able to identify the make, model, type or color and the extent of the damages.

   a. Again, if there is any question as to the material, collect, label and hold. Broken parts are more important than damaged parts. (Ex. Broken metal or a bent hub cap.)

   b. Parts of bodies of trucks are especially useful. They may identify a special type and make of truck. These may help you to locate particular vehicles.

3. Glass: Get the largest parts and several pieces if possible. You have a better chance of matching them with parts left on the vehicle.

4. Paint

   a. This is the most useful clue to the color of the hit and run vehicle.

   b. When paint is left from one vehicle to another or objects, samples can be scraped off and kept for scientific study.
      NOTE: Be careful not to scrape off paint from the object that was struck. This may contaminate the sample with the paint from the car on which it was found.

   c. Paint from chrome plated bumpers, head lamps, rims, door handles or any bright metal surface is best. It, too, is often easier to remove. Paint chips are especially good.

5. Things carried on a vehicle

   a. Evidence scattered or dropped at the scene of an accident may help to indicate where vehicles

9772

collided and where they came to rest and particularly clues for locating the vehicle after it has left the scene.

(1) Liquids of any type, location of accident and route
(2) Sand, gravel or other bulk materials which stay close to the area where they are dropped
(3) Rounded type materials generally scatter widely and are more helpful in identifying the vehicle than the collision point.
(4) Be careful not to assume they came from a hit and run vehicle, as they may have been dropped by another passing vehicle.

E. Pedestrian accidents

1. Fibers or hair

a. When a vehicle strikes a person, cyclist or large animal hard enough to cause death or injury, there usually is some bit of clothing or hair on the striking vehicle.

b. If it appears possible that the hit and run vehicle may have some evidence such as hair, clothing, etc., it would pay to get a sample from the hit and run victim for later identification. If the vehicle is located, this can later be scientifically matched.

c. In cases where there might be some quantity of blood on the hit and run vehicle, it would pay for the hospital to note on their records the victim's blood type.

d. Blood types can be scientifically matched to some extent from dried stains.

e. They will indicate if they are different or matched by type. You cannot say positively that they did come from the same person.

F. Collection and preservation of evidence

1. Cloth, hair, dirt, paint, glass, etc. should be placed in clean envelopes and sealed.

a. Avoid putting more than one kind of material in an envelope.

b. Label the envelopes or record the exact place it was found in respect to the road, vehicle or person. This will help you in reconstructing the accident.

c. The time, date, location, your name, etc. also will be able to prove identity of the material on the witness stand. (This can be done fairly easily by having the case number on the envelope.) The envelope will not be reopened for a chance of being tampered with.

d. Keep under lock until trial.

e. Chain of legal custody. Signed receipt or registered mail.

NOTE: In gathering evidence, do not advertise your findings as it may destroy your case. Word gets around.

9774

CHAPTER XIII

I. Recording Accident Information

A. Measurements to locate results of the accident

1. Reason for measurements

a. Careful measurements take the guess work out of locating things in your investigation. This will help you to testify with confidence and precision about your observations of where things were at the scene.

b. Aids in reconstruction

(1) Reconstruction will help you to find out how the accident happened. Without measurements, it is virtually impossible.
(2) Often a few measurements quickly and easily made will make photographs unnecessary and will reduce time needed to question drivers and witnesses later about positions of things at the scene.

NOTE: It is always better to have measurements that you never need than to need measurements that you do not have.

2. When to measure - Making measurements and sketches of most minor accidents is unnecessary. However, you expect to make urgent measurements in connection with:

a. All fatal accidents

b. All skidmarks

c. All accidents in which vehicle ran off road

d. Serious accidents where measurements may be needed for later prosecution

e. Accidents involving view obstruction outside of the vehicles. These are of special interest to traffic engineers.

f. Freak and serious accidents that you cannot explain

g. Accidents on the boundary lines of cities, counties or states and those partly on private property. This is to permit classifying the accident properly according to location.

9775

3. What needs measuring: To make a detailed accident diagram, you will need measurements for:

   a. Positions of vehicles where they come to rest after collision and vehicle parts

   b. The places where dead or injured persons lie after collision, in and out of vehicles. (Head injury can tell position)

   c. Point of collision or impact, running off pavement or shoulder

   d. Anything to show position of vehicle in road before collision. Tire marks, skidmarks and gouges are most common. (Skidmarks will show where vehicle came from.) If pictures are taken, know the position of the camera so the pictures can be compared with maps.

   NOTE: The purpose in measuring is to be able to relocate the position on the road if this becomes necessary.

4. Urgent measurements

   a. Some objects that you might want to measure will be moved or will disappear soon after the accident. Measurements will have to be taken.

   b. Some of these are temporary or short-lived.

      (1) Temporary - These actually last only minutes.
         (a) Skidmark shadows
         (b) Tire prints
         (c) Gasoline and water puddles
         (d) Debris or rubbish knocked from vehicles
         (e) Location of killed or injured
         (f) Location of damaged vehicle in traveled part of road

      (2) Short-lived - These may last several hours or even days.
         (a) Skidmark smears
         (b) Gouges on shoulders or banks
         (c) Oil and blood stains
         (d) Damage to fixed objects which will be repaired. (Ex. Signs)
         (e) Location of damaged vehicle off traveled part of road

9776

NOTE: Soon after getting to the accident, you must decide whether or not you will need measurements. Sometimes you will not be able to get measurements or temporary evidence right away. Some temporary evidence can be changed to short-lived by marking the position with a crayon. Don't neglect more urgent parts of an investigation just to make measurements.

B. Equipment - Only a few things are necessary to make satisfactory measurements in most accidents.

1. Tape measure at least 50 feet long

2. Pencil and yellow lumber marking crayon for writing on or marking pavement

3. Paper, preferably white, hard surfaced bond 8½" X 11" sheet padded. Knowledge and skill in using simple equipment is more important than additional equipment.

C. Precautions

1. Pacing is not very accurate but is much better than guessing.

2. Check tape and always keep it clean. Watch traffic when getting measurements.

3. When pacing, record your measurements as the number of steps.

4. Be careful when you are reading the tape.

D. Location measurements

1. You will need measurements to determine

a. The length, width, depth or height of something or to fix a location or position. In locating things accurately, you must measure from something permanent. Never measure from the point of impact. It is not a permanent object which can be found a week or a month later. Identify the position of object you measure from.

b. Small objects can be located well enough by measuring to their approximate centers.

(1) As bodies of persons, injured or killed, bicycles, gouges in the pavement, scrates, grooves, tire marks less than four feet long, piles of debris less than four feet across, parts of vehicles and damaged trees or posts

9777

(2) Vehicles
   (a) You will have to locate two points on each vehicle to fix its position.
   (b) Consider trailers and semitrailers as separate vehicles for this purpose.
(3) Long marks on the road surface are located by two or more points.
   (a) "If the mark is straight, one at each end is enough."
   (b) If the mark is curved, locate the center, if real long points, about every 20 feet.

E. Location by coordinates

1. Can be used to tie an object to a fixed point on or off the highway

2. One of these lines should be to a zero point.

3. Zero point is tied to a permanent point or landmark.

F. Location by triangulation

1. Can be used to tie an object to a fixed point on or off the highway

2. One of these lines should be to a zero point.

3. Zero point is tied to a permanent point or landmark.

9778

CHAPTER XIV

I. Legal Responsibilities

A. In connection with traffic accidents

1. A legal responsibility of a driver and others in connection with accidents differ considerably from state to state and city to city. It is important that you know what they are in your own community.

a. Almost every traffic accident has some legal implication. (Ex. The law requires that most all accidents be reported. Law suits for damages or injuries could be made.)

b. For most people, a traffic accident may be their first. Therefore, you can win genuine gratitude for yourself and respect for your organization simply by giving helpful information in a friendly manner.

2. Accident reporting by drivers

a. Calling police

(1) There are several reasons for rules requiring that the police be immediately notified in certain cases
(a) So the police can take immediate steps to handle the traffic problems that may develop
(b) To start an investigation before evidence and witnesses have disappeared
(c) So emergency vehicles can be sent (ambulance, fire trucks, tow trucks, etc.)

(2) In making out an accident report
(a) You are not sure of the amount of damage. Go ahead and fill it out to be on the safe side.
(b) Most states require the drivers to make reports (written) to the state for damages over certain amounts.
(c) Some states require separate reports for financial responsibility laws.
(d) A driver or owner is not required by law to notify his insurance company, but many companies have a clause in them. If the accident is not reported under certain conditions, the

9779

company will not pay a claim. Suggest to a driver that he should report it to his insurance company.

(e) Do not discuss civil liability or negligence in connection with suggestions to report to insurance companies.

B. Evading responsibility at scene

1. Every driver involved in an accident has a legal responsibility to do certain things.

   a. The first requirement of any driver involved in an accident resulting in personal injury, death or property damage is to stop as near as possible to the scene.

   b. Stay there until all his legal obligations have been fulfilled

   c. To be involved means that the driver is connected with the chain of events of the accident. It is not necessary for there to be actual contact for a driver to be involved. If he knows or should have known of the accident, he must stop and perform all the duties required by law.

NOTE: Help drivers meet responsibilities. When you investigate an accident at the scene, do everything you can to help the drivers fulfill their responsibilities.

2. Payment and punishment

   a. Perhaps the most annoying demand addressed to an investigator is from people who think someone else was responsible for the accident. They insist, "You've got to make him pay for my car."
      NOTE: You can't make anyone pay anything. Only courts can determine liability and assess damage. People think you can do everything. Only courts and insurance companies settle who pays.

   b. Demand to arrest - Often someone involved in an accident, and sometimes eye witnesses, will demand that you arrest a driver. Sometimes this is done in order to try to convince the officer or the driver's family and friends that he isn't wrong, as well as convincing himself.

9780

c. A person believes that if the driver is arrested, he will have to pay damages to keep out of jail. He confuses fines with civil damages and is only interested in someone else paying the bills.

C. Risk in trying to be helpful

1. Aid to injured - Are persons other than the driver involved required by law to give aid to the injured in an accident which occurs when they are present, or which they come upon shortly after it has happened?

a. "No one is required to assist a stranger." The fact that a person sees another person who is injured does not of itself impose on him any legal obligation to give relief or assistance.

b. North Carolina General Statute 20-166 (d) states no one can be responsible for injury resulting by trying to help in an accident scene as long as this injury is not a result of wanton conduct or intentional wrong doing.

D. Paying for ambulance service

1. In the event that you should call a doctor or ambulance to an injured person and he later cannot or will not pay for the service, you are not obligated.

a. In the absence of an agreement to pay, the one who calls on a doctor or ambulance to render services to another is not liable to pay. The same is true for a wrecker.

b. The mere fact of calling such service when the person calling is under no legal obligation to do so is no implication of promise to pay.

E. Charges for additional damages

1. Suppose in trying to get an injured person out of a car, put out a fire, or move the car out of the traffic, you damaged the car.

a. Would you have to pay?
(1) The same rule applies here as in the other questions. While there is no legal obligation for you to render assistance, you must exercise ordinary care in what you are doing or otherwise

you may render yourself liable for damages caused by begligence.

(2) Responsibility depends on who you are.

b. Does it make any difference to the foregoing question whether I am a police officer or insurance investigator, a relative or friend?

(1) Very much so.

(a) The ordinary person is under no legal obligation to render aid or assistance.

(b) However, an officer of the law, whose duty is to protect the public, does have an obligation. There may be such a duty on the part of a relative under certain circumstances.

(2) All should exercise ordinary care and are liable for further injury resulting from lack of proper care on his part.

c. When you are acting on someone's authority to remove vehicles, injured, etc., you will not be held liable for charges if you act in the best interest.

NOTE: The law imposes an obligation upon everyone who attempts to do something for another to use ordinary care and skill.

2. Duties of a police officer

a. Police have a general duty, nearly always specified by laws or ordinances, to enforce the law.

b. In connection with accidents, policemen must seek information to determine whether any law has been violated. If you believe a law has been violated, it is your duty as an officer of the law to get the evidence to prove the violation. It does not have to be a traffic violation - any kind of violation.

NOTE: References to laws: The exact responsibilities in connection with traffic accidents may be found in your state motor vehicle code or other additional requirements may be found in your city traffic ordinance.

9782

CHAPTER XV

I. Case Preparation and Testifying

A. How cases are decided

1. Respectable courts will not convict without sufficient evidence.

a. Do a thorough job of preparing case.

b. Bring in enough evidence to prove charges.

2. Trials are contests in persuasion with facts as weapons.

3. Cases of violations arising from accidents should be handled by qualified prosecutor.

a. Present all the facts to him.

b. Give him all available evidence.

c. See that all evidence is properly preserved for use in the trial.

d. Let him decide what to use in the case and what to leave out.

e. Evidence must be well presented to be effective.

4. Conferences with the prosecutor are most helpful in preparation of the case.

a. Regular meetings produce the best results when there are several cases.

b. Purpose of conferences is to insure that both of you have same understanding of case and are in agreement on strategy for presenting it.

c. In conferring, be entirely frank and honest with the prosecutor.

B. Testifying in court

1. Must know the rules of evidence

a. Can determine with the prosecutor what evidence is likely to be admitted

9783

b. Evidence must be well presented to be effective.

2. Must know how to conduct yourself

C. Common court situations - three kinds

1. Probable cause hearing

2. Trial without a jury

3. Jury trial

D. Appearance and behavior in court - Everyone in court forming an opinion of officer

1. General appearance

a. Well-groomed

b. Coat buttoned

c. Conservatively dressed

d. Sit properly, erect and relaxed

e. Bring only what you need in court (only notes on case in hearing) - notes should be where they are easily reached.

2. Manner - Dignified

3. Quality of voice

a. One reasonably understood

b. Clear and loud enough to be heard

4. Self control - Keep your wits and temper

5. Promptness of witness's reply

a. Answer questions as soon as you reasonably can.

b. Have a reasonably short period between question and answer.

c. If the question is not clear, ask that it be repeated.

6. Accuracy

a. Clearness of speech

(1) Short sentences
(2) Answer responsively to questions

9784

b. Brevity of statement - Do not make a speech

c. Selection of words - especially of descriptive phrase

7. Pronunciation - Speak clearly, watch slurring of words or running together.

8. Knowledge of subject

a. Have case properly prepared

b. Have clear, accurate notes

9. General statements

a. Look at defense council when he speaks to you.

b. Do not repeat perfectly audible statements.

c. Do not use affected nervous laughs.

d. Avoid unnecessary affected minute accuracy.

e. Stay away from the word "exactly" - use "similar".

E. Presenting your facts

1. Simply present facts.

2. Tell what you saw or discovered under permissible rules of evidence.

a. No case justifies departure from truth to obtain a conviction.

3. Be sincere and respectful.

4. Know courtroom procedure.

5. Be properly prepared.

a. Notes, reports, physical evidence, etc.

b. Do not try to memorize your testimony.

6. Look at the examiner when being questioned, but direct answer to judge or jury.

F. Cross examination

1. A legitimate and necessary part of any trial

2. The right to test the truth of witnesses' statements - One of the most important guarantees of our system of justice.

3. Purpose

   a. To search out the truth

   b. Expose ignorance or curruption

   c. Expose bias or malice on part of witness

   d. Without cross examination, the court would be forced to accept whatever any witness might choose to say with no means of checking the truth of the story or why the witness told it or if it should be believed.

4. Don't be aggressive or volunteer information not requested.

9786

CHAPTER XVI

I. Assisting in Prosecution

A. Bringing traffic violators to trial

1. Prosecution

a. The legal proceeding instituted in a court of law for determining the innocence or guilt of a person charged with an offense

(1) Citation
(2) Arrest
(a) On view
(b) Warrant

b. Successful prosecution requires:

(1) Good investigation
(2) Careful preparation

c. To penalize a violator may require efforts of:

(1) Police - to detect violator and cite or arrest violator to bring him into court
(2) Public prosecutor - the district or other official attorney who prosecutes the case in court
(3) Court - a judge and sometimes also a jury charged with the duty of deciding whether a violation has, in fact, been committed and what the penalty shall be

d. Responsibility of police officers for prosecution of violators:

(1) Essential assistance to prosecutor which is determined by
(a) How well you made investigation
(b) Power of observation
(c) Collecting and preservation of evidence
(d) Recording facts, reports, notes, etc.
(e) Knowledge, ability and presentation of testimony
(2) Understanding prosecutor's duties and something about the law under which violators are prosecuted will make it easier for you to do your part in bringing offenders to justice

9787

(a) Trial: A proceeding before a court governed by certain rules to determine the facts and insure that just verdicts are reached
   (1-1) two or more parties involved in disagreement
   (2-2) each has an opportunity to present evidence
(b) Parties to a trial
   (1-1) state or municipality on one side represented by prosecutor
   (2-2) defendant charged with a violation represented by defense attorney

(3) Duties of others involved in a trial
   (a) Judge: Primarily responsible for determining responsibility, for determining the correct application of the law and for seeing that trial proceedings are carried on in accordance with established rules
   (b) Jury: Responsible for weighing evidence and testimony presented in a trial
      (1-1) decide guilt or innocence of the defendant on this basis
      (2-2) without a jury, the judge has this responsibility
   (c) Prosecuting attorney: Represents the state or municipality in all criminal trials. He is responsible for presenting the state's evidence to the jury in such a manner that all available facts are known.
   (5) Defense attorney: Represents the defendant and has the obligation to make sure the defendant's rights and interests are protected during the trial
   (6) Witness: The "eyes and ears" of the judge and jury. He presents the facts within the rules established for court procedure.

B. Knowledge of law

1. Every officer needs a basic understanding of

   a. Traffic laws and rules

   b. Laws of arrest

   c. Rules of evidence

9788

2. Understanding helps you to

   a. Recognize violations more readily

   b. Prepare proper citations and charges

   c. Question witnesses properly

   d. Gather legally acceptable evidence

   e. Discuss case intelligently with prosecutor

   f. See a case to its proper conclusion in court

3. Elements of violation

   a. Traffic violations consist of a number of elements or parts which must be proven in court to convict

   b. Source of information for traffic violation elements

      (1) State motor vehicle code
      (2) City or municipal ordinances

   c. Example: Speeding elements

      (1) Accused must be driving a motor vehicle
      (2) Offense must take place on a public street, highway, public institution or place, providing parking space for customer
      (3) Vehicle must be in excess of stated limits or which is not reasonable and and prudent for existing conditions

C. Assisting the prosecutor - Establish a working relationship with prosecutor

   1. Present served cases for prosecutor to handle

   2. System for reporting facts to the prosecutor

   3. Make good quality arrests

   4. Remember the chain of evidence

   5. Know proper court procedure

   6. Be available for trial dates

   7. Keep prosecutor informed of the aims and objectives of program

9789

D. Adjudication and penalization

1. Make records available to court.

2. Maintain proper attitudes.

3. Realize that the judge is bound by law and legal principles.

4. Personal appearance

E. Other factors to consider which affect enforcement productivity

1. Must have adequate personnel

2. Must have adequate supervision to assure uniformity

3. Reporting of conditions

4. Departmental policies

5. Use of scientific aids

6. Working conditions and officer morale

7. Quality of all police activity

8. Nature and extent of inter-department cooperation

9. Public relations and public support

10. Adequate vehicles and equipment

11. Non-productive assignments

9790

DESCRIPTORS - *STUDY GUIDES; *TECHNICAL ILLUSTRATION; *TRADE AND INDUSTRIAL EDUCATION; *PROMOTION (OCCUPATIONAL); MILITARY TRAINING; MILITARY PERSONNEL; DRAFTING; DRAFTSMEN; VOCATIONAL EDUCATION; ENGINEERING DRAWING; VISUAL ARTS; *SUPPLEMENTARY TEXTBOOKS

ABSTRACT - Developed by the Training Publications Division of the Naval Personnel Program Support Activity, this study guide is for use by Navy and Naval Reserve personnel who are seeking advancement to the rate of Illustrator Draftsman Third Class or Illustrator Draftsman Second Class. The first chapter discusses the scope of the rating, and succeeding chapters provide information pertaining to: (1) mathematics, (2) machine, structural, mechanical, and electrical drawings, (3) lettering, (4) technical illustrations, (5) color, and (6) visual presentations. The material is illustrated by pictures and diagrams and a reading list and subject index are included. (GEB)

VT 012 764

PREFACE

This book is intended to serve as an aid for men who are seeking to acquire the theoretical knowledge and the operational skills required of candidates for advancement to the rate of Illustrator Draftsman Third Class or Illustrator Draftsman Second Class. As one of the Navy Training Courses, it was prepared by the Training Publications Division, Naval Personnel Program Support Activity, Washington, D.C., for the Bureau of Naval Personnel. Technical assistance was provided by the Illustrator Draftsman School, Port Hueneme, California.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

CHAPTER 1

THE JOB AHEAD

This training course is designed to help you meet the qualifications for advancement to Illustrator Draftsman Third Class or Illustrator Draftsman Second Class. It presents information on the drawing techniques which you will be required to perform and the materials and instruments which you will use as a member of one of the Group VI ratings: the Illustrator Draftsman.

The first chapter deals with the scope of the Illustrator Draftsman rating, the enlisted rating structure, advancement in rating and administration pertaining to the Illustrator Draftsman. It is strongly recommended that you study this chapter carefully before beginning intensive study of the remainder of this training course.

Chapter 2 of this manual presents a general overview of the mathematics and mechanics used in drafting. Chapter 3 concerns the tools, instruments and equipment used in line drafting. Chapter 4 introduces you to the general drafting practices used in the rating. Chapter 5 covers the development of surfaces. Chapter 6 describes machine and structural drawing. Chapter 7 describes the systems drawings you will learn such as plumbing, heating, ventilation and electrical drawings. Chapter 8 describes the office machines and equipment most generally found in all graphic shops. Chapters 9 through 19 cover the more illustrating subjects such as lettering in chapter 9. Chapter 10 covers basic materials and how to use them. Chapter 11 shows how to draw the basic forms. Chapter 12 covers principles of drawing human figures. Chapter 13 describes composition and design in illustrating. Chapter 14 explains perspective for the illustrator. Chapter 15 covers advanced line and tonal painting. Chapter 16 introduces you to the principles of color. Chapter 17 describes shop procedures and production. Chapter 18 covers cartooning. Chapter 19 describes visual presentations.

THE ENLISTED RATING STRUCTURE

The two main types of ratings in the present enlisted rating structure, are general ratings and service ratings.

General ratings identify broad occupational fields of related duties and functions. Some general ratings include service ratings; others do not. Both Regular Navy and Naval Reserve personnel may hold general ratings.

Service ratings identify subdivisions or specialties within a general rating. Although service ratings can exist at any petty officer level, they are most common at the PO3 and PO2 levels. Both Regular Navy and Naval Reserve personnel may hold service ratings.

THE ILLUSTRATOR DRAFTSMAN RATING

The Illustrator Draftsman is a general rating at all levels.

SCOPE OF THE RATING

The scope of the Illustrator Draftsman rate is as follows: Illustrator Draftsmen design and prepare drawings and illustrations for presentation and reproduction; letter and sketch for illustration purposes; produce signs, posters, charts, graphs, training aids, and illustrations; demonstrate knowledge of media and methods of preparing art copy for reproduction; reproduce art copy by the silkscreen method; enlarge and/or reduce drawings using such aids as coordinates, pantographs, opaque and overhead projectors; operate reproduction machines; prepare, correct, edit, and file ship and aircraft,

97982

mechanical, electrical, electronic, and machine drawings, tracings, sketches, plans, blueprints, and statistical data from information provided; make computations required for the performance of illustration drafting to cover general mathematics, mensuration, and geometry. Cut, layout, and mount photography.

TYPES OF BILLETS

As an Illustrator Draftsman, you may expect to be assigned to duty both with units of the Fleet and at shore activities. The shore stations at which you will actually do your work may be at various locations around the world.

In the Atlantic area you may be assigned to duty in Italy, England, or Spain, to mention a few. You may work at some of the numerous bases on islands in the Caribbean group.

In the Pacific area you may be assigned to duties in Hawaii, Japan, Guam or the Philippines.

There are several units of the Fleet which utilize Illustrator Draftsmen, and many are assigned to the various Fleet staffs.

PRACTICAL LEADERSHIP ASPECTS

The principles of military and inspirational leadership for petty officers are covered in Military Requirements for PO 3 & 2, NavPers 10056-A. The practical leadership exercised by a PO3 or PO2 is that leadership which relates to his technical capacity--in fact it is on-the-job leadership.

This type of leadership requires, in the first place, a complete knowledge of the technical subject-matter. You must have this, not only to perform your own technical functions, but also to be able to give necessary technical instruction to the team which happens to be under your charge. In addition to a complete knowledge of technical subject-matter, you must have the capacity for breaking a given mission down into its logical subphases and for assigning these subphases to the team in accordance with individual ability and aptitude.

A principle which has large application in technical leadership might be called the responsibility principle. You must yourself develop a sense of responsibility for ensuring that everything necessary to successful completion of a mission is carried out, and you must develop a similar sense of responsibility in every member of the team.

Suppose, for example, that you are in charge of a job and you have a three-man crew in your shop. You have the ultimate responsibility for seeing that all of your equipment is in proper working order. You can't, of course spend all of your time making constant inspections on the equipment and still have time to perform your other functions. You can however, and you must, assign a particular man the responsibility of the upkeep and maintenance of a particular piece of equipment or category of items. This man must be made to realize the extent of his responsibility—must be shown, for example, the dire results of finding an indispensable item of equipment out of order when its use is absolutely essential for completion of a job.

ADMINISTRATION

Illustrating and line drafting in the Navy is done for such a variety of purposes and under so many difficult conditions that it is difficult to lay down any hard and fast rules about the organization of a drafting room. Many ships and shore activities have billets for only one or two Illustrator Draftsmen, and they become a part of one of the main divisions.

Maintenance of Graphic-Drafting Room

As a PO3 or PO2, you will assume the different jobs required to keep the graphic-drafting room and its equipment in shape to (1) get the job done quickly and (2) create habits of orderliness and cleanliness in the man. It is your job to assign these jobs and to see that things are kept up to snuff.

It is always important to see that equipment and instruments are kept in good condition and to impress this fact upon the men under you. Bad equipment and instruments mean inefficiency. Any Illustrator Draftsman worth his salt sets a high value on good work habits and care of equipment. Even as a striker you should have begun to feel a professional pride in keeping equipment clean and in good working condition.

Filing Systems

When a filing system is established, it should be one that is adopted to the needs of the activity using it. Therefore, no hard and fast rules can be laid down on filing. It is the responsibility of the PO in charge to establish

the filing system to be used at his activity and you may be the leading PO even at the 3rd or 2nd class level. The efficiency of the system will depend on your judgment. You will have the responsibility for seeing that the material is filed in the manner best adopted to the particular needs of your activity.

You may use a numerical or alphabetical sequence for your filing. A catalog containing a number or letter assigned the work and a brief description of the work and its location should be easily accessible. The files should be in the charge of one man, and all removals and returns should be made by him. It will also be his responsibility to keep track of all movements of the material in case another request is made for the same material. Once a piece of material is filed in the wrong place, it is the same as lost.

All files should be kept up to date. Old obsolete material should be destroyed to make room for newer up-to-date material.

Records and Correspondence

It is a good idea to maintain only as many records as you can conveniently keep up to date. A record that is not kept up to date is worse than useless. But, if you have a large section to supervise, you may need to keep a number of records and to delegate the responsibility for keeping some of them to others. Even if your section is small, you should keep a catalog book for locating material in your files, and some sort of record of material used so that they can be conveniently reordered.

A log book of drawing numbers usually consists of a list of numbers down the left side of the sheet. As each number is assigned, the title of the drawing is written on the same line. The date of the assignment and the name of the Illustrator Draftsman to whom the job is assigned may also be given. The log serves as a permanent record of the number given each drawing, so that there is less chance of a drawing being completed with the wrong number or of two drawings receiving the same number. A cross index may also be kept by drawing title or subject on 3 x 5 cards. However, if the cards are not kept up to date the system will soon fall into disuse.

The print record has several purposes. It is a means of keeping track of prints so that out-of-date prints can be quickly located and destroyed. It is also of value as a record of work performed. It may be kept as a log in which orders for prints are recorded, along with the name of the ordering activity, the drawing number and its title, the number of prints made, and the date of delivery. This same information can be kept in a card file instead, with cards filed by drawing number or by drawing title.

A drawing job sheet serves as a check on work progress. The following are suggested as headings for the sheet:

Drawing No.	Title	Started	By	Completed

When you are in charge of a drafting section one of your jobs may be the drafting of letters concerning drawings, prints, and so forth to be signed by your commanding officer or officer-in-charge. In this case, you should obtain the latest copy of the Navy Correspondence Manual, SECNAVINST 5216.5. It contains chapters and sections on typing practice and format, as well as chapters on writing practice.

Of special interest will be the chapter on developing a communication. In this chapter, you will find a discussion of the things to consider in planning a letter, with general outlines for letters which are intended to serve various purposes. Other valuable material in this chapter consists of sections on evaluating the letter, means of referring to a previous communication, and using abbreviations.

Supply

As a petty officer and Illustrator Draftsman, supply problems will affect you as it does nearly all departments of naval activities. For this reason, you should pay thorough attention to chapter 12, Military Requirements for Petty Officer 3 & 2, NavPers 10056-A. This chapter explains the types of material, how to identify parts or equipment, and the groups and classes to which different material is assigned.

In this supply chapter you will be given information on the different identification publications, COSAL, how to use the Federal Supply Catalog, procurement, forms to use in ordering supplies and surveying equipment no longer useable or needed. You are instructed in the proper custody and storage of material, and about the inventory of supplies.

Although normal channels of supply must be used whenever possible, some of the articles used in graphic-drafting shops cannot be acquired directly from all supply ships or supply depots, but will have to be ordered or purchased on the open market. For this reason, you should always anticipate your needs well in advance because it adds additional costs to buy on the open market.

In the area of making repairs of equipment, except for the very minor type of repairs, the maker of the equipment should be contacted, through the supply department, and the manufacturer's representative to make necessary repairs.

On any equipment where immediate repairs are necessary and the necessary repair parts are available, the repairs should be completed only after consulting the instruction book on the equipment. These instruction books supplied by the manufacturers are designed to aid you in making minor repairs and will also point out safety procedures necessary for your safety and the safety of the equipment.

ADVANCEMENT IN RATING

Some of the rewards of advancement in rating are easy to see. You get more pay. Your job assignments become more interesting and more challenging. You are regarded with greater respect by officers and enlisted personnel. You enjoy the satisfaction of getting ahead in your chosen Navy career.

But the advantages of advancing in rating are not yours alone. The Navy also profits. Highly trained personnel are essential to the functioning of the Navy. By each advancement in rating, you increase your value to the Navy in two ways. First, you become more valuable as a technical specialist in your own rating. And second, you become more valuable as a person who can train others and thus make far-reaching contributions to the entire Navy.

HOW TO QUALIFY FOR ADVANCEMENT

What must you do to qualify for advancement in rating? The requirements may change from time to time, but usually you must:

1. Have a certain amount of time in your present grade.
2. Complete the required military and professional training courses.
3. Demonstrate your ability to perform all the practical requirements for advancement by completing the Record of Practical Factors, NavPers 760.
4. Be recommended by your commanding officer, after the petty officers and officers supervising your work have indicated that they consider you capable of performing the duties of the next higher rate.
5. Demonstrate your knowledge by passing a written examination on (a) military requirements and (b) professional qualifications.

Some of these general requirements may be modified in certain ways. Figure 1-1 gives a more detailed view of the requirements for advancement of active duty personnel; figure 1-2 gives this information for inactive duty personnel.

Remember that the requirements for advancement can change. Check with your division officer or training officer to be sure that you know the most recent requirements.

Advancement in rating is not automatic. After you have met all the requirements, you are eligible for advancement. You will actually be advanced in rating only if you meet all the requirements (including making a high enough score on the written examination) and if the quotas for your rating permit your advancement.

HOW TO PREPARE FOR ADVANCEMENT

What must you do to prepare for advancement in rating? You must study the qualifications for advancement, work on the practical factors, study the required Navy Training Courses, and study other material that is required for advancement in your rating. To prepare for advancement, you will need to be familiar with (1) the Quals Manual, (2) the Record of Practical Factors, NavPers 760, (3) a NavPers publication called Training Publications for Advancement in Rating, NavPers 10052, and (4) applicable Navy Training Courses. Figure 1-3 illustrates these materials; the following sections describe them and give you some practical suggestions on how to use them in preparing for advancement.

The Quals Manual

The Manual of Qualifications for Advancement in Rating, NavPers 18068B (with changes), gives the minimum requirements for advancement to each rate within each rating. This

09801

ACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *	E1 to E2	E2 to E3	E3 to E4	E4 to E5	E5 to E6	†E6 to E7	† E7 to E8	† E8 to E9
SERVICE	4 mos. service—or completion of recruit training.	6 mos. as E-2.	6 mos. as E-3.	12 mos. as E-4.	24 mos. as E-5.	36 mos. as E-6.	36 mos. as E-7. 8 of 11 years total service must be enlisted. Must be permanent appointment.	24 mos. as E-8. 10 of 13 years total service must be enlisted.
SCHOOL	Recruit Training.		Class A for PR3, DT3, PT3. AME 3, HM 3			Class B for AGCA, MUCA, MNCA.		
PRACTICAL FACTORS	Locally prepared check-offs.	Records of Practical Factors, NavPers 760, must be completed for E-3 and all PO advancements.						
PERFORMANCE TEST			Specified ratings must complete applicable performance tests before taking examinations.					
ENLISTED PERFORMANCE EVALUATION	As used by CO when approving advancement.	Counts toward performance factor credit in advancement multiple.						
EXAMINATIONS	Locally prepared tests.		Navy-wide examinations required for all PO advancements.				Navy-wide, selection board, and physical.	
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)		Required for E-3 and all PO advancements unless waived because of school completion, but need not be repeated if identical course has already been completed. See NavPers 10052 (current edition).					Correspondence courses and recommended reading. See NavPers 10052 (current edition).	
AUTHORIZATION	Commanding Officer		U.S. Naval Examining Center			Bureau of Naval Personnel		
	TARS attached to the air program are advanced to fill vacancies and must be approved by CNARESTRA.							

* All advancements require commanding officer's recommendation.
† 2 years obligated service required.

Figure 1-1.—Active duty advancement requirements.

INACTIVE DUTY ADVANCEMENT REQUIREMENTS

REQUIREMENTS *		E1 to E2	E2 to E3	E3 to E4	E4 to E5	E5 to E6	E6 to E7	E8	E9
	FOR THESE DRILLS PER YEAR								
TOTAL TIME IN GRADE	48	6 mos.	6 mos.	15 mos.	18 mos.	24 mos.	36 mos.	36 mos.	24 mos.
	24	9 mos.	9 mos.	15 mos.	18 mos.	24 mos.	36 mos.	36 mos.	24 mos.
	NON-DRILLING	12 mos.	24 mos.	24 mos.	36 mos.	48 mos.	48 mos.		
TOTAL TRAINING DUTY IN GRADE †	48	14 days	14 days	14 days	14 days	28 days	42 days	42 days	28 days
	24	14 days	14 days	14 days	14 days	28 days	42 days	42 days	28 days
	NON-DRILLING	None	None	14 days	14 days	28 days	28 days		
PERFORMANCE TESTS				Specified ratings must complete applicable performance tests before taking examination.					
DRILL PARTICIPATION		Satisfactory participation as a member of a drill unit.							
PRACTICAL FACTORS (INCLUDING MILITARY REQUIREMENTS)		Record of Practical Factors, NavPers 760, must be completea for all advancements.							
NAVY TRAINING COURSE (INCLUDING MILITARY REQUIREMENTS)		Completion of applicable course or courses must be entered in service record.							
EXAMINATION		Standard exams are used where available, otherwise locally prepared exams are used.						Standard EXAM, Selection Board, and Physical.	
AUTHORIZATION		District commandant or CNARESTRA					Bureau of Naval Personnel		

* Recommendation by commanding officer required for all advancements.

† Active duty periods may be substituted for training duty.

Figure 1-2.—Inactive duty advancement requirements.

59803

Figure 1-3.—Materials used in preparing for advancement.

9804

manual is usually called the "Quals Manual," and the qualifications themselves are often called "quals." The qualifications are of two general types: (1) military requirements, and (2) professional or technical qualifications.

Military requirements apply to all ratings rather than to any one particular rating. Military requirements for advancement to third class and second class petty officer rates deal with military conduct, naval organization, military justice, security, watch standing, and other subjects which are required of petty officers in all ratings.

Professional qualifications are technical or professional requirements that are directly related to the work of each rating.

Both the military requirements and the professional qualifications are divided into subject matter groups; then, within each subject matter group, they are divided into practical factors and knowledge factors. Practical factors are things you must be able to DO. Knowledge factors are things you must KNOW in order to perform the duties of your rating.

The written examination you will take for advancement in rating will contain questions relating to the practical factors and the knowledge factors of both the military requirements and the professional qualifications. If you are working for advancement to second class remember that you may be examined on third class qualifications as well as on second class qualifications.

The Quals Manual is kept current by means of changes. The professional qualifications for your rating which are covered in this training course were current at the time the course was printed. By the time you are studying this course, however, the quals for your rating may have been changed. Never trust any set of quals until you have checked it against an up-to-date copy in the Quals Manual.

Record of Practical Factors

Before you can take the servicewide examination for advancement in rating, there must be an entry in your service record to show that you have qualified in the practical factors of both the military requirements and the professional qualifications. A special form known as the Record of Practical Factors, NavPers 760, is used to keep a record of your practical factor qualifications. This form is available for each rating. The form lists all practical factors, both military and professional. As you demonstrate your ability to perform each practical factor, appropriate entries are made in the date and initials columns.

Changes are made periodically to the Manual of Qualifications for Advancement in Rating, and revised forms of NavPers 760 are provided when necessary. Extra space is allowed on the Record of Practical Factors for entering additional practical factors as they are published in changes to the Quals Manual. The Record of Practical Factors also provides space for recording demonstrated proficiency in skills which are within the general scope of the rating but which are not identified as minimum qualifications for advancement.

If you are transferred before you qualify in all practical factors, the NavPers 760 form should be forwarded with your service record to your next duty station. You can save yourself a lot of trouble by making sure that this form is actually inserted in your service record before you are transferred. If the form is not in your service record, you may be required to start all over again and requalify in the practical factors which have already been checked off.

NavPers 10052

Training Publications for Advancement in Rating, NavPers 10052 (revised), is a very important publication for anyone preparing for advancement in rating. This bibliography lists required and recommended Navy Training Courses and other reference material to be used by personnel working for advancement in rating. NavPers 10052 is revised and issued once each year by the Bureau of Naval Personnel. Each revised edition is identified by a letter following the NavPers number. When using this publication, be sure that you have the most recent edition.

If extensive changes in qualifications occur in any rating between the annual revisions of NavPers 10052, a supplementary list of study material may be issued in the form of a BuPers Notice. When you are preparing for advancement, check to see whether changes have been made in the qualifications for your rating. If changes have been made, see if a BuPers Notice has been issued to supplement NavPers 10052 for your rating.

The required and recommended references are listed by rate level in NavPers 10052. If

9805
4080

you are working for advancement to third class, study the material that is listed for third class. If you are working for advancement to second class, study the material that is listed for second class; but remember that you are also responsible for the references listed at the third class level.

In using NavPers 10052, you will notice that some Navy Training Courses are marked with an asterisk (*). Any course marked in this way is mandatory—that is, it must be completed at the indicated rate level before you can be eligible to take the servicewide examination for advancement in rating. Each mandatory course may be completed by (1) passing the appropriate enlisted correspondence course that is based on the mandatory training course; (2) passing locally prepared tests based on the information given in the training course; or (3) in some cases, successfully completing an appropriate Class A school.

Do not overlook the section of NavPers 10052 which lists the required and recommended references relating to the military requirements for advancement. Personnel of ALL ratings must complete the mandatory military requirements training course for the appropriate rate level before they can be eligible to advance in rating.

The references in NavPers 10052 which are recommended but not mandatory should also be studied carefully. ALL references listed in NavPers 10052 may be used as source material for the written examinations, at the appropriate rate levels.

Navy Training Courses

There are two general types of Navy Training Courses. Rating courses (such as this one) are prepared for most enlisted ratings. A rating training course gives information that is directly related to the professional qualifications of one rating. Subject matter courses or basic courses give information that applies to more than one rating.

Navy Training Courses are revised from time to time to keep them up to date technically. The revision of a Navy Training Course is identified by a letter following the NavPers number. You can tell whether any particular copy of a Navy Training Course is the latest edition by checking the NavPers number and the letter following this number in the most recent edition of List of Training Manuals and Correspondence Courses, NavPers 10061. (NavPers 10061 is actually a catalog that lists all current training courses and correspondence courses; you will find this catalog useful in planning your study program.)

Navy Training Courses are designed to help you prepare for advancement in rating. The following suggestions may help you to make the best use of this course and other Navy training publications when you are preparing for advancement in rating.

1. Study the military requirements and the professional qualifications for your rating before you study the training course, and refer to the quals frequently as you study. Remember, you are studying the training course primarily in order to meet these quals.

2. Set up a regular study plan. It will probably be easier for you to stick to a schedule if you can plan to study at the same time each day. If possible, schedule your studying for a time of day when you will not have too many interruptions or distractions.

3. Before you begin to study any part of the training course intensively, become familiar with the entire book. Read the preface and the table of contents. Check through the index. Look at the appendixes. Thumb through the book without any particular plan, looking at the illustrations and reading bits here and there as you see things that interest you.

4. Look at the training course in more detail, to see how it is organized. Look at the table of contents again. Then, chapter by chapter, read the introduction, the headings, and the subheadings. This will give you a pretty clear picture of the scope and content of the book. As you look through the book in this way, ask yourself some questions: What do I need to learn about this? What do I already know about this? How is this information related to information given in other chapters? How is this information related to the qualifications for advancement in rating?

5. When you have a general idea of what is in the training course and how it is organized, fill in the details by intensive study. In each study period, try to cover a complete unit—it may be a chapter, a section of a chapter, or a subsection. The amount of material that you can cover at one time will vary. If you know the subject well, or if the material is easy, you can cover quite a lot at one time. Difficult or unfamiliar material will require more study time.

9806

6. In studying any one unit—chapter, section, or subsection—write down the questions that occur to you. Many people find it helpful to make a written outline of the unit as they study, or at least to write down the most important ideas.

7. As you study, relate the information in the training course to the knowledge you already have. When you read about a process, a skill, or a situation, try to see how this information ties in with your own past experience.

8. When you have finished studying a unit, take time out to see what you have learned. Look back over your notes and questions. Maybe some of your questions have been answered, but perhaps you still have some that are not answered. Without looking at the training course, write down the main ideas that you have gotten from studying this unit. Don't just quote the book. If you can't give these ideas in your own words, the chances are that you have not really mastered the information.

9. Use Enlisted Correspondence Courses whenever you can. The correspondence courses are based on Navy Training Courses or on other appropriate texts. As mentioned before, completion of a mandatory Navy Training Course can be accomplished by passing an Enlisted Correspondence Course based on the Navy Training Course. You will probably find it helpful to take other correspondence courses, as well as those based on mandatory training courses. Taking a correspondence course helps you to master the information given in the training course, and also helps you see how much you have learned.

10. Think of your future as you study Navy Training Courses. You are working for advancement to third class or second class right now, but someday you will be working toward higher rates. Anything extra that you can learn now will help you both now and later.

SOURCES OF INFORMATION

One of the most useful things you can learn about a subject is how to find out more about it. No single publication can give you all the information you need to perform the duties of your rating. You should learn where to look for accurate, authoritative, up-to-date information on all subjects related to the military requirements for advancement and the professional qualifications of your rating.

Some of the publications described here are subject to change or revision from time to time—some at regular intervals, others as the need arises. When using any publication that is subject to change or revision, be sure that you have the latest edition. When using any publication that is kept current by means of changes, be sure you have a copy in which all official changes have been made. Studying canceled or obsolete information will not help you to do your work or to advance in rating; it is likely to be a waste of time, and may even be seriously misleading.

GOVERNMENT PUBLICATIONS

Military standards for engineering drawings and for illustrations of technical manuals are published with MIL-STD publication numbers. Current standards are listed in the Department of Defense Index of Specifications and Standards, the use of which is described in detail in chapter 4.

You should obtain a copy of those standards pertaining to the work done in your command and should request that all of the standards currently applying to illustrative drafting be obtained for use in studying.

TEXTBOOKS

There is a wealth of information for the Illustrator Draftsman in phamphlets, handbooks, and texts emanating from manufacturers, technical and professional societies and private publishing houses. Some of these are Commercial Art Techniques, by S. Ralph Maurello; Engineering Drawing, 8th edition, by French; Technical Drawing, by Giesecke, Mitchell, and Spencer; Creative Illustration, by Loomis; and Screen Process, by Zahn.

9807 4088

CHAPTER 2

MATHEMATICS

As a draftsman, you must know how to measure distances accurately, scale distances on a drawing, reduce fractions to decimals, and find the area of a plane figure or the volume of a solid. This chapter includes a brief review of fractions and decimals, and gives a few of the basic formulas for finding area and volume. Unless you have a firm grasp of the basic operations of arithmetic, you cannot expect to be able to use mathematics successfully. If you can use numbers accurately and easily, you will find that mathematics is less difficult than you may have been led to suppose.

Mathematics is, as a matter of fact, very much like mechanical drawing in that, once you have a grasp of the principles, it becomes a matter of skill which can be acquired by practice. If you have never had occasion to use algebra, geometry, trigonometry, or logarithms, or have not had the occasion for some time, you will need to practice in order to develop the necessary skill. When you are using these tools steadily on the job, you will find that their use becomes almost second nature to you, so that problems which would otherwise be extremely complex can be solved quickly with a minimum of effort.

The Navy has prepared basic Navy Training Courses on mathematics. Two of these texts are Mathematics, Volume 1, NavPers 10069-B and Mathematics, Volume 2, 10071-A. These two texts cover all the mathematics required in the qualifications for advancement to DM3 and DM2. At the time of the writing of this DM 3&2 text, Mathematics, Volume 1, is undergoing revision and will be available several months after this text is published. Therefore, throughout this chapter, reference will be made to chapters in both the old NavPers 10069-B edition and the new NavPers 10069-C edition.

FRACTIONS AND DECIMALS

Any graduated instrument like a ruler is called a scale, although actually the set of graduations on it is the scale. When we speak of the scale of a drawing, we mean the ratio of the measurements on a drawing of an object to the same measurements on the object.

For example, suppose you are drawing an object which is 24 inches long, but there is only room on your paper for a drawing 12 inches long. If the object is drawn to scale in this space, 2 inches on the object will be represented by 1 inch on the drawing, and the drawing will be called a half-scale drawing. You could, of course, draw the object 6 inches long on the paper, and then 4 inches on the object would be represented by 1 inch on the drawing. The drawing would be called a quarter-scale drawing.

Notice that a half-scale drawing is not half the size of the object. It is only a quarter the size of the object, because the dimensions in each direction are halved. For the same reasons, a quarter-scale drawing is only 1/16 the size of the object.

A draftsman must deal with problems of scale constantly. When measuring distances with scales and when dimensioning drawings, you will use common fractions and decimal fractions. There will be times when, in order to determine the dimensions of a part, you must add, subtract, multiply, or divide fractions. Sometimes it will be necessary to change common fractions to decimal fractions (usually called decimals) and vice versa. Refer to figure 2-1 for a table of decimal equivalents to some

9808 C080

common fractions. Keeping such a table on hand will save you time, but you should know how to perform these operations yourself.

If you have not used your arithmetic lately, especially working with fractions, review the appropriate chapters in Mathematics, Vol. 1. Common fractions are covered in chapter 3 of NavPers 10069-B or chapter 4 of NavPers 10069-C. Decimals, including percentage and the reduction of common fractions to decimals and vice versa, are covered in chapter 4 of NavPers 10069-B or chapter 5 of NavPers 10069-C.

Figure 2-1.—Reduction table for fractions and decimals.

ALGEBRA

Algebra is an extension and completion of arithmetic. It does not involve an abrupt change into a distinctly new field, but rather provides a smooth transition into many branches of mathematics with a continuation of knowledge already gained in basic arithmetic. All the rules of algebra agree with those of arithmetic, and a great many of them are identical. Algebra enables us to write the rules of arithmetic, using symbols that are not only simpler and more concise but of a general nature rather than specific. Through algebra we are able to investigate the properties of numbers and to deal with their relations and combinations. Algebra also enables us to solve problems not even remotely possible by arithmetic means.

Study chapters 8 through 11 of Mathematics, Volume I NavPers 10069-B for details and practice problems in algebra. Or, refer to chapter 9 through 12 of NavPers 10069-C.

RATIO AND PROPORTION

Almost every computation which involves determining an unknown value on the basis of known values involves the solution of proportional equation. For example, if b represents the length of the base of a rectangle and h represents the height, then the formula for the area A is: A = bh. This is itself a proportional equation—that is, an equation showing two equal ratios, as: $\frac{A}{1} = \frac{bh}{1}$. It follows that, if $A = bh$, then $b = \frac{A}{h}$. This is likewise, of course, a proportional equation containing two equal ratios, as: $\frac{b}{1} = \frac{A}{h}$. It follows again that, if $A = \frac{b}{h}$, then $h = \frac{A}{b}$. This is, of course, again a proportional equation.

The whole of chapter 15 of NavPers 10069-B (chapter 13 in NavPers 10069-C) is devoted to an explanation of ratio and proportion, the solution of proportional equations, and the closely related subject of variation. In addition to this knowledge, you should develop the ability to recognize a computational situation as one that is solvable by proportional equation. Practically any problem involving the conversion of measurement expressed in one unit to the equivalent in a different unit is solvable by proportional equation. Similarly, if you know the quantity of a certain material required to produce a certain number of units of product, you can determine by proportional equation the quantity required to produce any given number of units.

In short, it is difficult to imagine any mathematical computation involving the determination of unknown values on the basis of known values that is not solvable by proportional equation.

Your knowledge of equations need not extend beyond that required to solve linear equations—

9809 8080

that is, equations in which the unknown appears with no exponent higher than 1. The equation $4x \div 7 = \frac{15}{6}$ for example, is a linear equation because the unknown (technically known as the "variable") x appears to only the 1st power. The equation $x^2 \div 2x = -1$, however, is not a linear but a quadratic equation, because the variable x appears to the second power.

Chapter 10 of NavPers 10069-B (chapter 11 in NavPers 10069-C) is devoted to an explanation of linear equations in one variable. Chapter 11 of NavPers 10069-B (chapter 12 of NavPers 10069-C) is devoted to an explanation of linear equations in two variables.

CONVERSION OF WEIGHTS AND MEASURES

A unit of measurement is simply an arbitrary length, area, or volume, generally adopted and agreed upon as a standard unit of measurement. The basic standard for linear measurement, for example, is the meter, and the actual length of a meter is, in the last analysis, equal to 1,650,763.73 wavelengths of orange-red light of krypton-86.

As a DM, you will not be working with all the units described in this chapter, and therefore you need not attempt to memorize them all. Many are included simply to show that units are arbitrary and that there are many different kinds of units in use.

Units of Linear Measure

In the United States and most other English-speaking countries the most commonly used basic unit of linear measurement is the foot, a unit which amounts to slightly more than three-tenths of the international meter. In what is called "engineer's" measurement, the foot is subdivided decimally—that is, into tenths, hundredths, or thousandths of a foot. In what is called "carpenter's" measurement, the foot is subdivided into twelfths called inches, and the inch is further subdivided into even-denominator fractional parts, as: 1/2 in., 1/4 in., 1/8 in., 1/16 in., and so on.

Fractions or multiples of the basic 1-ft unit are used to form larger units of linear measure, as follows:

1 line	=	0.66 ft
1 yard	=	3.00 ft
1 rod, pole, or perch	=	16.50 ft
1 Gunter's chain	=	66.00 ft
1 engineer's chain	=	100.00 ft
1 statute mile U.S.	=	5280.00 ft
1 nautical mile (international)	=	6076.10 ft

A unit of linear measurement called a "vara," of Spanish and Portugese orgin, was formerly used to measure land boundaries in those areas of the U.S. which were at one time under Spanish control. The length of a vara varies in different parts of Arizona, California, Florida, New Mexico, and Texas from slightly less than 33 in. to slightly more than 33 in.

In many of the countries of the world the most commonly used basic unit of linear measure is the meter. The length of a meter was originally designed to equal (and does equal very nearly) one tenmillionth part of the distance, measured along a meridian, between the earth's Equator and one of the poles. A meter equals slightly more than 109 yd.

The big advantage of the metric system is the fact that it is a decimal system throughout—that is, the fact that the basic unit can be both subdivided into smaller units decimally and converted to larger units decimally, by simply moving the decimal point in the appropriate direction. Names of units smaller than the meter are indicated by the Latin prefixes deci- (one-tenth), centi- (one-hundredth), milli- (one-thousandth), and micro- (one-millionth), as follows:

1 decimeter	=	0.1 meter
1 centimeter	=	0.01 meter
1 millimeter	=	0.001 meter
1 micrometer	=	0.000001 meter

Names of units larger than the meter are indicated by the Greek prefixes deca- (ten), hecto- (one hundred), kilo- (one thousand), myria- (ten thousand), and mega- (one million), as follows:

1 decameter	=	10.00 meters
1 hectometer	=	100.00 meters
1 kilometer	=	1,000.00 meters
1 myriameter	=	10,000.00 meters
1 megameter	=	1,000,000.00 meters

Units of Area Measurement

In the English and metric systems, area is most frequently designated in units which consist of squares of linear units, as: square inches, feet, yards, miles; or square meters or kilometers. For land area measurements in the English system, however, other units have been

9810

1f8e

developed in various ways. Some of these, with their equivalents in square feet, are as follows:

1 perch = 272.25 sq ft (this is the equivalent of a square rod or pole)
1 rood = 10,890 sq ft (this is the equivalent of 1/4 acre)
1 acre = 43,560.00 sq ft

An equilateral rectangular acre measures 208.71 ft on a side. There are 640 acres in a square mile.

Units of Angular Measurement

For DM purposes, an angle may be roughly defined as two straight lines which lie in the same plane and meet at a point. The point of meeting is called the apex of the angle, and the two straight lines are called the sides.

Again for DM purposes it may be said that the size of an angle is designated according to the size (measured in units of arc) of the arc (segment of the circumference of a circle with center at the apex) lying between the sides. (The circumference is the whole distance around a circle.)

According to this DM definition, the largest conceivable angle is the angle comprised in a single complete circle. Trigonometrically speaking, angles larger than this are conceivable.

The unit of arc most commonly used to measure angles in the English-speaking countries is the degree, representing a 360th part of the circumference of the total circle around the apex. A degree is subdivided into 60 minutes, each of which contains 60 seconds. Seconds are subdivided decimally into tenths, hundredths, and so on.

Angular measurement in grads is an aspect of the metric system of measurement, and is used mostly in those countries which make general use of the metric system. The circumference of the complete circle is divided into 400 equal intervals called grads, each of which is subdivided decimally into tenths, hundredths, thousandths, and so on. As there are 400 grads in 360 degrees, it follows that there are 400/4, or 100 grads in 90 degrees, and 1 grad therefore equals 0.9 degrees, which equals 54 minutes.

Angular measurement in mils is used principally for pointing and training guns in directing artillery fire. The circumference of the complete circle is divided into 6400 equal intervals called mils, and the mil is subdivided decimally into tenths, hundredths, and so on. As there are 6400 mils in 360 degrees, it follows that there are 1600 mils in 90 degrees, and that 1 mil equals 0.059 degrees, or an angle measuring about 0° 3' 36". The significance of this to gunnery lies in the fact that this is an angle which will subtend 1 yard at a range (target distance) of 1000 yds. Therefore, another common definition of mil is: the angle which subtends 1 yd at 1000 yds.

Units of Weight

The units of weight most frequently used in the U.S. for weighing all commodities except precious stones, precious metals, and drugs are the units of the so-called "avoirdupois" system. Avoirdupois units of weight are as follows:

437 1/2 grains (gr)	=	1 ounce (oz)
16 ounces (oz)	=	1 pound (lb)
100 pounds (lbs)	=	1 hundredweight (cwt)
2000 pounds (or 20 cwt)	=	1 ton (T)

Precious stones and precious metals are usually weighed in the U.S. by the system of "troy" weight, in which there are 12 rather than 16 oz in the pound. Drugs are weighed by "apothecaries" weight, in which there are also 12 oz in the pound.

In conjunction with the metric system of measure, there is a metric system of weight. The basic unit of this system is the "gram", which contains 15.432 grains. The grain was originally supposed to be equal to the weight of a single grain of wheat. The gram of 15.432 grains is also used in the avoirdupois, troy, and apothecaries' system of weights.

Multiples and subdivisions of the basic unit of the metric weight (the gram) are named in accordance with the usual metric system of nomenclature, as follows:

0.000001 gm	=	1 microgram
0.001 gm	=	1 milligram
0.01 gm	=	1 centigram
0.10 gm	=	1 decigram
10.00 gm	=	1 decagram
100.00 gm	=	1 hectogram
1000.00 gm	=	1 kilogram

A kilogram weighs about 2.2 lbs avg. A "metric ton" equals 1000 kilograms, which equals about 1.1 tons avg.

Board Measure

Board measure is a method of measuring lumber in which the basic unit is a board foot

0180
9811

(bf). A board foot is an abstract volume 1 ft long by 1 ft wide by 1 inch thick. The chief practical use of board measure is in cost calculations; lumber is sold by the board foot just as sugar is sold by the pound.

There are several formulas for calculating the number of board feet in any given length of lumber of given section dimensions. Because lumber dimensions are most frequently given by length in feet and width and thickness in inches, the following formula is probably the most practical:

$$bf = \frac{\text{thickness in in. x width in in. x length in ft.}}{12}$$

Board measure is calculated on the basis of the nominal, not the actual, section dimensions. The actual section dimensions of (for example) 2 x 4 stock which is finished on all four surfaces (F4S) are about 1 5/8 in. thick by 3 5/8 in. wide. Nevertheless, the computation for the number of bf in (say) 300 ft of 2 x 4 would be as follows:

$$\frac{\overset{1}{\cancel{2}} \times \overset{2}{\cancel{4}} \times \overset{100}{\cancel{300}}}{\underset{\underset{\underset{1}{\cancel{3}}}{\cancel{6}}}{\cancel{12}}} = 200 \text{ bf}$$

Liquid Measure

In the U.S. the basic unit of liquid measure is the gallon, which has a volume of 231 cu in., or 1.6 cu ft. The gallon is subdivided into smaller units as follows:

1 gallon = 4 quarts
1 quart = 2 pints
1 pint = 4 gills

Units larger than the gallon in liquid measure are as follows:

1 barrel = 31.5 gallons
1 hogshead = 63 gallons or 2 barrels

For petroleum products the standard barrel contains 42 gals.

In the metric system the basic unit of liquid measure is the liter, equal in volume to a cubic decimeter, or about 61 cu in. There are 3.785 liters in a U.S. gallon.

Following the usual metric system of nomenclature, subdivisions and multiples of the liter are as follows:

0.000001 liter = 1 microliter
0.001 liter = 1 milliliter
0.01 liter = 1 centiliter
0.10 liter = 1 deciliter
10.00 liter = 1 decaliter
100.00 liter = 1 hectoliter
1000.00 liter = 1 kiloliter

Temperature Measure

Temperature is commonly measured in the U.S. by the Fahrenheit system devised by the German scientist Fahrenheit. In this system the freezing point of water is 32° F and the boiling point 212° F.

In many scientific pursuits the "centigrade" system is preferred. In this system (which was devised by the Swedish scientist Celsius, and is therefore sometimes called the Celsius system) the freezing point of water is 0° C and the boiling point 100° C. You can see that the centigrade system has a distant relationship to the metric system of measure.

Conversion of Units

To convert a measure expressed in terms of one unit to the equivalent in terms of a different unit is, when you know the ratio between the units, a simple proportional equation problem.

Let us suppose, for example, that you want to convert a linear distance in engineer's measure (feet and decimals of feet) to the equivalent in carpenters measure to the nearest 1/8 in. Suppose that the original distance is 12.65 ft. This means "12 ft and 65 hundredths of a foot." In carpenter's measure the foot is divided into inches, or twelfths of a foot. You want to determine first, then, how many twelfths of a foot there are in 65 hundredths of a foot. The original ratio is $\frac{12}{100}$. The proportional equation solution is:

$$\frac{x}{65} = \frac{12}{100}$$

$$x = \frac{12 \times 65}{100} = \frac{780}{100} = 7.8$$

Therefore there are 7.8 in. in 0.65 ft. The next step is to determine how many eights of an in. there are in 0.8 in., that is, in 8 tenths of an in. The initial ratio is $\frac{8}{10}$, and the proportional equation solution is:

$$\frac{x}{8} = \frac{8}{10}$$

$$x = \frac{8 \times 8}{10} = \frac{64}{10} = 6.4$$

9812 6189

Therefore there are (rounded off) $\frac{6}{8}$ in., or $\frac{3}{4}$ in., in 0.8 in. In 12.65 ft, then, there are 12 ft 7 3/4 in. to the nearest $\frac{1}{8}$ in.

In converting from engineer's to carpenter's measure, or vice-versa, you may, when working to the nearest 0.01 ft or $\frac{1}{8}$ in., use the following tables of decimal equivalents of inches from 1 through 11 and decimal equivalents of the common carpenter's-measure subdivisions of the inch.

1 in. = 0.08 ft
2 in. = 0.17 ft
3 in. = 0.25 ft
4 in. = 0.33 ft
5 in. = 0.42 ft
6 in. = 0.50 ft
7 in. = 0.58 ft
8 in. = 0.67 ft
9 in. = 0.75 ft
10 in. = 0.83 ft
11 in. = 0.92 ft
1/8 in. = 0.01 ft
1/4 in. = 0.02 ft
1/2 in. = 0.04 ft
3/4 in. = 0.06 ft

Using these values, you can convert decimals of a foot to inches carpenter's measure, or inches carpenter's measure to decimals of a foot, very easily. To convert (for example) 0.37 ft. to inches carpenter's measure you have:

0.33 ft = 4 in.
0.04 ft = 1/2 in.
0.37 ft = 4 1/2 in.

To convert (say) = 7 3/8 in. carpenter's measure to engineer's measure you have:

7 in. = 0.58 ft
3/8 in. = (3 x 0.01) = 0.03 ft
7 3/8 in. = 0.61 ft

For a great many types of conversions there are tables in which you can find the desired values by inspection. Such tables may be found in drafting and engineering handbooks. These handbooks frequently also contain tables of constants, in which a large number of conversion factors are given. A conversion factor is a number which, multiplied by a value expressed in terms of one unit, will produce the equivalent value expressed in terms of a different unit. The factor for converting linear feet to miles, for instance, is 0.00019. If you multiply 5280 ft by 0.00019, you get 1.00 miles.

When you know the ratio between two different units, you can easily work out your own conversion factor. For example: you know that the ratio of degrees to mils is $\frac{9}{160}$. The conversion factor for converting degrees to mils is the number of mils in 1 degree, which is $\frac{160}{9}$, or 17.8 The conversion factor for converting mils to degrees is the number of degrees in a mil, which is $\frac{9}{160}$, or 0.0562. Some typical conversion factors are:

Lineal feet	x	0.00019	= miles
Lineal yards	x	0.0006	= miles
Square inches	x	0.007	= square feet
Square feet	x	0.111	= square yards
Square yards	x	0.0002067	= acres
Acres	x	4840.0	= square yards
Cubic inches	x	0.00058	= cubic feet
Cubic feet	x	0.03704	= cubic yards

Typical equivalents include the following:

U. S. gallons in 1 cubic foot	= 7.4805
Feet in 1 meter	= 3.280833
Inches in 1 meter	= 39.37
Square feet in 1 acre	= 43560.00

POWERS AND ROOTS

Raising a number to a power means multiplying the number by itself a certain number of times. Taking the root of a given number means determining what number must be multiplied by itself a certain number of times to result in the given number. Any number is a higher power of a given root; the number 9, for example, constitutes 3 raised to the second power, commonly called "3 squared," which is written 3^2. It follows that the square root of 9 is 3. A particular power is indicated by a small numeral called an exponent; the small 2 on 3^2 is an exponent. A particular root is indicated by the so-called radical sign $\sqrt{}$, together with a small numeral called the index of the root. The expression $\sqrt[3]{27}$, for example, means "the cube root of 27". For a square root, however, the index symbol is usually left off the radical sign.

9813 S18e

Powers, roots, exponents, radicals, and most of the significant arithmetical operations connected with the same are described in detail in chapter 5 of NavPers 10069-B (or in chapter 7 of NavPers 10069-C). Appendix D of NavPers 10069-B contains a table which gives the squares, cubes, square roots, and cube roots of numbers from 1 to 1000. The use of this table, then, will give you the square or cube root of any number containing not more than 3 digits. For numbers containing more than three digits, any roots or powers (including fractional roots and powers) may be obtained by the use of logarithms.

LOGARITHMS

The arithmetical operations of multiplication and division of numbers and the extraction of roots or the determination of powers of numbers, can be greatly simplified by the use of logarithms. There are two types of logarithms: "natural" (also called "Naperian") logs, and "common" logs. Natural logs are used mainly in higher mathematics. You will be working exclusively with common logs.

Common logs are explained in NavPers 10069-B, chapter 7, and 10069-C, chapter 8, and are also discussed in NavPers 10071-A, chapter 8. The logarithm of a given number is the exponent indicating the power to which another number called the base must be raised to produce the given number. For example: since $3^2 = 9$, 2 is the logarithm of 9 to the base 3. Common logs are logs to the base 10. Since $10^2 = 100$, 2 is the log of 100 to the base 10. When we write log 360 = 2.55630, we understand this to mean $10^{2.55630} = 360$.

GRAPHS

A graphical presentation can usually be grasped much more quickly and clearly than a table of figures. Graphs, which are sometimes called charts and sometimes called diagrams, are consistently used in engineering work and publications and as visual aids in Navy training programs.

There are many kinds of graphs. They may be divided roughly into two categories: engineering graphs and illustrative graphs. A draftsman in any of the engineering fields should know the basic types of coordinate paper, how to plot accurately, and how to draw curves. The illustrator should have this knowledge and these skills, and he should also know how to present the information in the form of visual aids to be used in briefings and training sessions.

This chapter introduces types of graph paper and the mathematics involved in plotting graphs. The use of French curves to draw graphs is covered in chapter 3. The illustrative aspects of charts and graphs are presented in chapter 19.

Coordinates

Coordinates are quantities which designate the position of point in relation to a given reference frame. Telling someone that the post office is "two blocks north of Main Street and three blocks east of Broadway" is using coordinates. Coordinates are often used in conjunction with a grid, which is a network of uniformly spaced straight lines intersecting at right angles. Figure 2-2 shows a grid. The reference frame consists of horizontal and vertical base lines. Each base line in this example is divided into units of measurement; each of the units is further divided into tenths. Call the direction of the vertical base line "North"; call the direction of the horizontal base line "East". The intersection of the base lines is called the origin and has coordinate values of zero-zero; that is, 0.0 North and 0.0 East.

Figure 2-2.—Coordinates of a point on a grid.

9814 6180

Figure 2-2a.—X and Y coordinate designations.

Point "P" is located 3 units plus one-tenth of a unit more, or 3.1 units, above the horizontal base line. P is also 2.6 units east of the vertical base line. The coordinates of P, therefore, are 3.1 North and 2.6 East.

On the grid shown in figure 2-2 the lines create rectangles; therefore grid coordinates are also called rectangular coordinates. There are various systems for designating the elements of grid coordinate system. Figure 2-2a shows the X and Y coordinate designation system in which x and y are the distances from the base lines to the coordinated point. It is customary to give the x value first and then the y value when identifying a point by x and y coordinates. The base lines divided the map into four areas or quadrants. Measurements up from and to the right of the origin are given positive, or plus, values; but measurements down and to the left are given negative, or minus, values (fig. 2-3). Therefore the x values and y values will be either positive or negative as shown in the illustration. For illustrative purposes, however, you would most likely be dealing only with positive quantities, therefore, the axes would be at the left and bottom, with only enough space left on the margins for the lettering. Generally the intersection of the axes is the zero point for both the vertical and horizontal axes, but on illustrative graphs, where paper saving is important, this is not always true.

Figure 2-3.—Plus and minus coordinates.

Figure 2-4.—Polar coordinates.

Since coordinates are any quantities which designate position, all coordinates are not necessarily grid coordinates; figure 2-4 illustrates a system of polar coordinates wherein point P is located by an angle and a distance.

Graph Paper

Coordinate paper is available with several types of printed grids, of which the most generally used are the rectangular, logarithmic, and semilogarithmic. (See fig. 2-5.) The rectangular coordinate paper (fig. 2-5a) is available in many different patterns of divisions; for example: 5, 8, 10, 16, or 20 spaces to the inch. The logarithmic paper (fig. 2-5b) is divided by the log scale on both axes; the semilog paper shown in figure 2-5c has equal divisions

9815-188

Figure 2-5.—Coordinate paper. A. Rectangular. B. Logarithmic. C. Semilogarithmic.

Figure 2-6.—Logarithms and corresponding members on a rule.

along the abscissa (horizontal) axis and log divisions along the ordinate axis. The mantissas of the logs of the numbers 1 through 10 have values from 0 to 1; this relationship is shown graphically in figure 2-6. Since only the characteristic changes for numbers less than 1 and greater than 10, the relationship pictured holds true for all of the tens groups; that is, 10 to 100, 100 to 1000, and so on. Note that the spaces between the numbers are not equal. On the graph paper, the number of ruled divisions between digits decreases as the digits get closer together. For example, note that along the ordinate in figure 2-5c there are 10 ruled divisions between 1 and 2 but only 5 spaces between 5 and 6; 1.5 is plotted 5 spaces above 1, but 5.5 is plotted 2 1/2 spaces above 5. Always carefully count the spaces when you plot values on log paper.

Plotting Graphs

Before you plot a graph, study the limits of the data to be plotted. Select a scale which is big enough to give you a meaningful picture but small enough so that the graph won't run off the paper. Figure 2-7 shows a graph on rectangular coordinate paper with labels indicating the terms used for the various elements.

In plotting the data on the graph locate each point with a dot and enclose each dot with a small circle, triangle, or square. Then draw a curve through the points. When the points do not fall so that they form a smooth curve, connect each point to the next with a straight line. Then draw a curve through these lines in such a way that the sum of the areas of the arcs formed by the lines on one side of the curve is approximately equal to the sum of the areas of the arcs on the other side.

The lettering on the graph should make the meaning clear to the reader. The grid lines should be broken out for lettering when this is possible, and when several curves are close together, leaders with captions should be used to distinguish the different lines.

The plotting of the conventional bar graph (fig. 2-8, for example) generally requires the

9816 7180

knowledge of fractions or decimals and the use of a scale. The plotting of a pie chart (fig. 2-9) requires the knowledge of angular measure and the use of a protractor (described in chapter 3). Each individual item becomes a slice out of the pie. Since the 360 degrees of the circle equal 100 percent, 180 degrees equal 50 percent, 90 degrees equal 25 percent, and so on.

GEOMETRY

Geometry is that branch of mathematics which investigates the relations, properties, and measurement of solids, surfaces, lines, and angles; the theory of space and of figures in space. Mensuration is that branch of geometry concerned with finding length of lines, areas of surfaces, and volumes of solids.

As a draftsman you work with geometry constantly. Subsequent chapters in this book present porcedures for constructing geometrical figures with drawing instruments. This chapter identifies various plane and solid figures and explains how to compute areas and volumes.

Plane Figures

A geometrical surface has length and breadth. It has no thickness. A plane is a real or imaginary surface in which a straight line between any two points lies wholly in that surface. A plane surface is a surface on which every point lies in the same plane. Plane figures are plane surfaces bounded by either straight lines or curved lines.

Figure 2-10 shows some common plane figures. Refer to the illustration while you study the following terms, definitions, and statements relating to the plane figures depicted and indentified.

Figure 2-10.—Common plane figures.

A triangle is a three-sided figure.

A right triangle contains a right angle; that is, two of the sides are perpendicular—at right angles to one another.

A scalene triangle has unequal sides and angles.

An equilateral triangle has equal sides; the angles are also equal—therefore an equilateral triangle is also an equiangular triangle.

An isosceles triangle has two equal sides (and also two equal angles).

An obtuse triangle has an angle greater than 90°).

A quadrilateral is a four-sided figure.

A parallelogram has opposite sides which are equal and parallel (parallel lines are equally distant from each other at all points).

A square is a parallelogram whose sides are equal and perpendicular.

A rectangle is a parallelogram whose sides are perpendicular but unequal.

A rhombus is a parallelogram whose sides are equal but not perpendicular.

A trapezoid is a quadrilateral which has only two parallel sides.

A trapezium is a quadrilateral which has no parallel sides.

A polygon has many sides.

A regular polygon has equal sides.

A pentagon has five sides.

A hexagon has six sides.

A heptagon has seven sides.

An octagon has eight sides.

A circle is a closed curve every point of which is equally distant from a fixed point inside called the center.

Every point on an ellipse satisfies the following condition with respect to two fixed points which are called foci: the sum of the distances from a point on the curve to the foci is constant.

Areas of Plane Figures

Figure 2-11 shows a rectangle measuring 10 ft x 8 ft, divided up into units of area measure, each consisting of 1 square foot. If you counted the units, one after the other, you would count a total of 80 units. However, you can see that there are 8 rows of 10 units, or 10 rows of 8 units. Therefore, the quickest way to count the units is simply to multiply 10 by 8 or 8 by 10.

You could call the 10-ft dimension the length and the 8-ft dimension the width, in which case you would say that the formula

for determining area of a rectangle is $A = \ell w$, or $A = w\ell$. Or you could call the 10-ft dimension the base and the 8-ft dimension the altitude (meaning height), in which case your formula for area of a rectangle would be $A = ba$.

If the length of a rectangle is given as 4 feet and the width as 6 inches, convert the feet to inches before you substitute the numerical value for the letter in the formula. Since 4 feet equals 48 inches, the formula using the measurements will read: A = 48 in. x 6 in., or A = 288 square inches. Or, converting the 6 inches to 0.5 ft, A = 4.0 ft. x 0.5 ft = 2.0 square feet.

When you use a formula for area, like $A = \ell w$, the length and width must be expressed in the same units of measurement, and the area will be expressed in terms of square units of this measurement.

Figure 2-11.

Figure 2-12.—Graphic illustration of the area of a square in terms of square units.

Figure 2-13.—Area A is two feet square. It contains four square feet. B is two square feet.

Figure 2-14.

The formula $A = \ell w$ can be used to find the area of a square. Figure 2-12 shows a square with sides 3 inches long and an area of 9 square inches. When we write the formula for the area of a square, we may use s for side, instead of ℓ and w, and write A = s x s, or $A = s^2$. The square of a number is always the number multiplied by itself.

Do not confuse square feet with feet square. A surface two feet square is twice as large as a surface of two square feet. (See fig. 2-13.) Two feet square means two feet long and two feet wide. On the other hand, two square feet means two squares, each one of which is one foot square.

Figure 2-14 shows a triangle consisting of one-half of the rectangle shown in figure 2-11. It is obvious that the area of this triangle must equal one-half of the area of the cor-

Figure 2-15.

Figure 2-16.

responding rectangle, and the fact that it does can be demonstrated by geometrical proof. Therefore, since the formula for the area of the rectangle is A = ba, it follows that the formula for the triangle is A = 1/2ba.

The triangle shown in figure 2-14, because it is half of a corresponding rectangle, contains a right angle, and is therefore a right triangle. In a right triangle the altitude is the length of one of the sides. The triangle shown in figure 2-15, however, is an oblique triangle, so-called because all of the angles are oblique—that is, not right angles.

Now, a perpendicular DC drawn from the base AB to the apex of the angle at C divides the triangle into two right triangles, ACD and BCD. The area of the whole triangle equals the sum of the areas of ACD and BCD. The area of ACD equals 1/2 (AD) (DC), and the area of BCD equals 1/2 (DB) (DC). Therefore, the area of the whole triangle equals $\frac{AD}{2}(DC) + \frac{DB}{2}(DC)$, or $DC(\frac{AD + DB}{2})$. But since AD + DB = AB, it follows that the area of the whole triangle equals $DC(\frac{AB}{2})$. The length of AB is called the base (b), and the length of DC the altitude (a); therefore, your formula for determining the area of an oblique triangle is again A = 1/2ba.

Figure 2-16 shows a rhomboid ABCD. If you erect a perpendicular FC from AD to the apex of the angle at C, and another from BC to the apex of the angle at A, you will create the right triangles ABE and FCD, and the rectangle AECF. It can be shown geometrically that the right triangles are similar and equal.

You can see that the area of the rectangle AECF equals the product of AF x FC. The area of the triangle FCD equals 1/2(FD)(FC). Because the triangle ABE is equal and similar to FCD, the area of that triangle also equals 1/2(FD)(FC). Therefore, the total area of both triangles equals (FD)(FC). The total area of the rhomboid equals the area of the rectangle AECF.

Figure 2-17.

Figure 2-18.

The total area of the rhomboid equals (AF)(FC) + (FD)(FC), or (AF + FD)(FC). But AF + FD equals AD, the base. FC equals the altitude. Therefore, the formula for the area of a rhomboid is A = ba. Here again you must remember that the altitude in a rectangle corresponds to the length of one of the sides, but in a rhombus or rhomboid it does not.

Figure 2-17 shows a trapezoid ABCD. If you erect perpendiculars EB and FC from AD to B and C, you create the right triangles ABE and FCD and the rectangle EBCF. The area of the trapezoid obviously equals the sum of the areas of these figures. FC can be shown geometrically to be equal to EB.

The area of ABE equals 1/2(AE)(FC), the area of FCD equals 1/2(FD)(FC), and the area of EBCF equals (EF)(FC). Therefore, the area of the trapezoid equals $(\frac{AE}{2} + \frac{FD}{2} + EF)(FC)$, or $(\frac{AE + FD + 2EF}{2})(FC)$. However, 2EF equals EF + BC. Therefore, the area of the trapezoid equals $(\frac{AE + EF + FD + BC}{2})(FC)$. But AE + EF + FD equals AD. Therefore, the area of the trapezoid equals $(\frac{AD + BC}{2})(FC)$. AD and BC are considered to be bases; we'll call them b_1 and b_2. FC equals the altitude a. Therefore, the formula for area of a trapezoid is $A = (\frac{b_1 + b_2}{2})(a)$. This can be stated in words as "average base times altitude."

Figure 2-18 shows you how you can determine the area of area of a trapezium, or of any polygon, by reducing to triangles. The dotted line connecting A and C divides the figure into the triangles ABC and ACD. The area of the trapezium obviously equals the sum of the areas of these triangles.

Figure 2-19 shows how you could cut a disk up into 12 equal sectors. Each of these sectors would constitute a triangle, except for the slight curvature of the side which was originally a segment of the circumference of the disk. If this side is considered the base, then the altitude for each triangle equals the radius (r) of the original disk. The area of each triangle, then, equals $\frac{br}{2}$, and the area of the original disk equals the sum of the areas of all the triangles. The sum of the areas of all the triangles, however, equals the sum of all the b's, multiplied by r and divided by 2.

Figure 2-19.—Triangle sectors.

But the sum of all the b's equals the circumference (c) of the original disk. Therefore, the formula for the area of a circle can be expressed as $A = \frac{cr}{2}$. However, the circumference of a circle equals the product of the diameter times π (3.14159...). The diameter equals twice the radius; therefore, the circumference equals $2\pi r$. Substituting $2\pi r$ for c in the formula $A = \frac{cr}{2}$, we have $A = \frac{(2\pi r)(r)}{2}$,

Figure 2-20.
